ROYAL GARDENS KEW.

*Period.*

THE  
JOURNAL OF HORTICULTURE,  
COTTAGE GARDENER,  
AND  
HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

CONDUCTED BY  
ROBERT HOGG, LL.D., F.L.S.

Established

in 1848.

VOLUME XXVI. THIRD SERIES.  
JANUARY—JUNE, 1893.

LONDON:  
PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

LONDON :  
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,  
171. FLEET STREET.

## TO OUR READERS.

---

PERHAPS the most interesting subjects to the majority of our readers at the moment these lines are penned are Rain and Roses.

A break in the drought is welcome to all; concern for the Roses—the condition of the blooms and the character of the shows—a matter of anxiety with many.

We have passed through a period, which may be termed the chief growing season of the year, that will long remain in the memory, for the absence of rain has been remarkable and abnormal.

Also the Rose season will be remembered as, perhaps, the earliest on record, and there are at least some rosarians who lost most of their best blooms before the shows at which they hoped to win high honours came round.

The loss of Roses at the time they are most wanted is, we will say, a disappointing fact, but the loss of wealth by loss of rain, as represented by the crops (or their absence) in gardens and fields is in not a few instances a grave calamity.

Let us see what the absence of rain means through the period referred to—namely the greater part of March till towards the end of June.

It may be said with an approximation to the actual facts of the case, that every acre plot of land over a great extent of country has lost nearly 600 tons of rain, or more than 135,000 gallons of water that usually falls from the clouds. Every garden of five acres has lost about 3000 tons, or 675,000 gallons. Small home farms of twenty acres have lost, broadly speaking, 12,000 tons of rain, or two and three-quarter million gallons. Farms of 100 acres have dried up under a deficiency of 60,000 tons, or thirteen and a half million gallons; and parishes of 1000 acres have suffered by the deprivation of no less than 600,000 tons, or one hundred and thirty-five million gallons of water which generally falls to refresh the earth during the periods indicated.

This plain narrative is sufficient to show the great difficulties which have beset cultivators, as it also demonstrates the extreme value of a good water supply in gardens.

The drought has also emphasized the soundness of the teaching that has often been advanced by our experienced coadjutors—namely, deep culture, enriched soil, summer mulching, or loose surface tillage.

We sympathise with all who have suffered by the drought, congratulate those who have met it so bravely, and earnestly hope that as compensation usually follows adverse visitations, so a reward is in store for those who have laboured well and are now waiting for their recompense.

**A**NOTHER year! Ah! how differently, my brothers and sisters of the craft which I think far more deserves the title of "gentle" than that to which old Izaak Walton assigned it I can understand the selfish enjoyment of the angler, for I have fished in my day, and even caught a salmon; but how anyone can call that gentle whose chiefest enjoyment consists in the agonies of an unfortunate fish, and the longer these agonies are prolonged the greater the enjoyment, I cannot understand. What shall we call, then, the craft which has to do with the care and forethought and continued attention which mark the horticulturist? Yes, we are the members of the gentle craft. But let that pass; we are on the threshold of another year, and as we step across it how different are the feelings with which we do so. The young, as they cross over it with firm and elastic step, full of all the possibilities of youth—and to youth everything is possible—see but the brilliant hues of spring and summer. The aged, on whom the experience of life has left its mark, step over with some vague and undefined dread of what may happen; the autumn tints of declining years and the frosted landscape of winter more engage their thoughts. But, alas! I am drifting away into sermonising instead of dealing directly with the subject which should engage my pen—the retrospect of the past year and the prospects of the coming one. I think all who have ever taken the trouble to read what I have written in the Journal for so many years (and I believe I am its oldest regular contributor) know that I am no pessimist, that I believe hopefulness is a precious thing, and that, while the experience of many years may sober, it need not darken the prospect, whether we look backward or forward.

In looking back at the conditions of horticulture during the past year we have to, as usual, think of the exhibitions, for it is around them (however much some pessimists may decry them) that the chief interest of those who are interested in the various branches of gardening centres; and as far as the metropolis is concerned the chief event has been the International Horticultural Exhibition; which was so successfully carried out at Earl's Court. As might have been expected, when so accomplished a landscape gardener as Mr. Milner undertook the laying out of the grounds, and Mr. W. Marshall the arrangements of the Shows, a great success was achieved. I think everybody must have been charmed with the laying out of the grounds, while the magnificent exhibitions of flowers, fruit, and vegetables surpassed anything that has been seen in the metropolis for many years. One's memory has to go back to the opening Show, at that ill-starred speculation, the Alexandra Palace, to find a parallel, and that was only a single exhibition, whereas throughout the whole season the ball was kept rolling, and the last was said to be the best of any. I was not able to see them all, but those which I did see were admirable. They required more space, but as a rule the plants showed to great advantage, while every kind of consideration was given to those who, either as exhibitors or judges, were present. There was not a great deal of internationality, it is true—there rarely is; but the presence of many of the most distinguished foreigners from France and Belgium at any rate redeemed its character in this respect. I believe large crowds visited the gardens, but when I hear that Buffalo Bill carried

off £55,000 as his share of the results, I am inclined to think that this was the chief attraction for visitors.

It was probably partly owing to this cause that the Crystal Palace Company dispensed with two of their Shows. There was no summer Show and their great autumn fruit Show was dispensed with. The National Rose Society and the National Dahlia Society held their Exhibitions as usual there, and both were a success, although the Electrical Exhibition sadly interfered with the symmetry of the arrangements. Of the Aquarium I desire to say but little. Of all the miserable places for a flower show that is the worst. The wretched light, especially in November, when the Chrysanthemum Society holds its Exhibition, the disgusting stench of bad tobacco which pervades the atmosphere, and the bellowing of showmen each trying to shout down the others, contrive to make it the least enjoyable place I have ever known for such things. The Royal Botanic Society has also curtailed its Exhibitions.

The Royal Horticultural Society still deserves and receives the support of all that is worth having in the horticultural world with the exception of the attendance of the general public. It is true the Drill Hall is not the most desirable place for a show, but it is the best that the Society can obtain, and I fear the scheme of a grand horticultural hall has collapsed, and this is a reproach on the horticulturists of the kingdom. It only proves what many people have expressed—that London, through its vastness, is about the worst place in which to start anything that has to look for general support. As one goes into that hall on any of the fortnightly meetings, and sees the truly grand displays of the choicest and most novel productions of the best gardens in and around London, and then looks at the handful of visitors who come to see them, one cannot but feel this reproach. There are many Fellows of the Society residing in or near the metropolis, and if only they or some members of their family would attend, although it might not add to the funds of the Society, it would unquestionably minister to the cheerfulness of the meetings. Of the magnificent Exhibition in the Temple Gardens it is superfluous to speak; it equalled, if it did not surpass, its predecessors; and when one recollects that all this grand collection is gathered together without any prize list it speaks volumes for the hold which the R.H.S. has on horticulturists throughout the kingdom, both amateurs and professional, and the confidence which its present management inspires, a confidence mainly owing to the admirable qualities of its Honorary Secretary, who by his courteous manner, good common sense, and thorough business habits has done more to lift the Society out of the slough than anyone else.

In the provinces there have been some changes, the most notable of which was the abandonment for the present year of the great Whitsuntide Exhibition at Manchester. The Botanical Society received a most tempting offer for the use of the Gardens for the summer, and as it would lift them out of many difficulties they accepted it, but I believe that it is the intention of the Council to renew their "suspended animation" this year, and that the Whitsuntide Exhibition of 1893 will equal if not surpass its predecessors. Other provincial societies have had a varied tale to tell, but all bear witness to the increased and increasing interest taken in gardening. It is a pleasing thing to be able to record the ever-increasing love and taste for hardy border flowers and alpinists. People sometimes talk of the old-fashioned flowers, but if anyone takes the trouble of looking through a catalogue of such flowers he will be surprised to find how few, comparatively speaking, of these flowers are found amongst them; for the same zeal which has led collectors to penetrate the virgin forests of South America in search for Orchids, or Borneo for its *Nepenthes*, has led others to the Himalayas, the Caucasus, the Alps, the Carpathians, and other mountain ranges in search of hardy plants, and have for many years been adding gem after gem to our gardens, and also solving many difficulties in their cultivation. There seems to be but little cessation if any in the love—shall I

call it the rage?—for Orchids, the most notable event in connection with which has been the sale of the large collection at Blenheim, of which the death of the Duke of Marlborough caused the dispersion towards the close of the year. It was more remarkable for its extent than for the rarity of the plants, although some fetched high prices, and the whole realised about £5000. But while one grower thus passes out of our view others come in to fill the gap, and there does not seem at present any likelihood of the love for them waning. Many of them are so exquisite for personal and house adornment that in this direction there is an ever-increasing demand.

Amongst other flowers the Chrysanthemum, Begonia, and Dahlia still maintain their popularity, while the Carnation as a border flower has advanced considerably. The new productions in border Carnations, raised by Mr. Martin Smith at home and Mr. Ernest Benary abroad, have enriched us with many beautiful varieties, and I think we may reasonably hope for better things to come. The advance has been most noticeable, especially in the yellow grounds, and those who, like myself, can remember when some half-dozen of these constituted our whole supply, may well be astonished at the wealth of varieties we now possess. The Chrysanthemum, especially the Japanese section, may be said, I think, to be the most popular flower of the day. Easily grown; coming into flower at a time when, except to the comparatively rich, flowers are scarce; accommodating themselves to the back garden of the artisan as well as to the conservatory of the wealthy, it is no wonder that its votaries are so many and their enthusiasm so great; and then so wonderful are its capabilities that we cannot say where we may stop as to either size or colour. Indeed as to the former I fear we are in danger of running into excesses in this matter. When you get a flower like *Etoile de Lyon* some 15 or 18 inches across, one may fairly say that size has been obtained at the expense of refinement.

I fancy there is a lull in the taste for Begonias, except perhaps for bedding out; and in truth it is difficult to see what more remains to be done. In size we have I believe exceeded both in singles and doubles; in fact, I do not see the beauty of these immense flowers. What we do want to see, and what I hope we may get, is a race that will, like the *Gloxinia*, hold itself erect, as does that most exquisite double flower of Cannell's, *Rose-bud*. We have also an amount of striped or flaked flowers, and this will probably make them of increased interest. The lovers of the Dahlia, too, are still energetic in its cultivation, and if the production of novelties does not keep pace with that of former years it is probably from the same cause—that it does not seem likely we can advance much further. There seems to be a limit in these things. The *Show Pelargonium*, the *Fuchsia*, the *Cineraria*, and the *Calceolaria* have passed through these various phases, and now no one looks for any novelties in these flowers. The *Auricula* still maintains its character as the florists' flower of the few, and although there have been additions to the ranks of its growers, especially in the south, they are after all but a handful in comparison with those who cultivate the Rose, or the Chrysanthemum, or the Dahlia. But few additions are made to it, and these additions are but the shadows that flit across us and then vanish away to reappear a dozen years hence. With the exception of selfs we rarely get any that will push the older varieties out of the way. The late Mr. Woodhead's varieties, and two or three of Mr. Simonite's, are desirable; but otherwise the older sorts still hold the fort.

The flowers which have been certificated during the past year have been as numerous, if not more so, than ever; there have been altogether awarded this honour 648. This does not imply that all are new, for we have such plants as *Fritillaria aurea* included amongst them, but in the case of garden varieties it does imply that they are novelties, and it will give some idea in which direction popularity lies when I say that amongst Orchids there have been thirty-eight *Cypripediums* and thirty *Cattleyas*, showing that

these are the two most popular of this gorgeous and beautiful class of plants. Then there have been certificated thirty-nine Begonias, twenty-four Carnations and Picotees, forty-six Chrysanthemums, forty-six Dahlias, twenty Gladioli, and thirteen Roses. We must be prepared to find that the greater number of these have but an ephemeral existence, and perhaps some of them may never be heard of again. I do not think that there has been any such excitement over any new plant as we have witnessed in former years. A good deal of interest was aroused in a flower of the singular *Aristolochia gigas* exhibited at one of the meetings at the Drill Hall, but it is not a new though a most remarkable flower.

The character of the past season must have rather damped the ardour of those who have looked to fruit-growing as the salvation of the British farmer, for it has been of a very varied character; for while in general Plums, Apples, and Pears, and especially the latter, have been a failure, enormous crops have been gathered in some places, and those who have been thus favoured have realised large sums of money. The most valuable event in connection with this was the grand trophy exhibited to the Lord Mayor's Show by the Fruiterers' Company, and arranged by Mr. George Bunyard of Maidstone. It was composed entirely of British-grown fruits, most tastefully arranged, and formed one of the most attractive features of the day.

The Gardeners' Guild has evinced new symptoms of life, and is diligently aiding in the general attention given to horticulture, while the two societies which are intended to help the aged and the orphan, the Gardeners' Royal Benevolent Institution and the Gardeners' Orphan Fund, are in a very satisfactory condition. The Horticultural Club, too, which for eighteen years has played a not unimportant part in bringing together into social contact all classes of horticulturists, also had a prosperous year. Its meetings have been well attended, and its advantages much appreciated.

And now I come to what is ever a sad thing, to call over the death roll and see who have dropped out of our company during the past year. While many good and excellent men have passed away, many of whom have been much valued amongst a limited class, there has been no very prominent name removed from amongst us. To me, the greatest blank is that left by my old friend Margottin père of Bourg la Reine, near Paris. He was my first Rose acquaintance abroad some nearly forty years ago, and I ever retained a great regard for the honest man that he was. He had raised some good Roses in his time, and although many of them have passed out of cultivation as exhibition varieties, Jules Margottin and others will, I think, long retain their position as garden Roses. His two latest additions, *Gloire de Bourg la Reine* and *Gloire de Margottin*, are two of the most brilliant flowers we have, and if not up to the front rank as exhibition Roses, will be very valuable ones for the garden. He was just my own age, and many a pleasant chat have I had with my old friend, and it is somewhat curious that when I had definitely determined that I would not again cross the Channel he should have passed away. Another name associated with my early gardening reminiscences was Ambrose Balfe, who died just at the close of last year, and who for a long period had been the admirable Secretary of the Royal Horticultural Society of Ireland. In Mr. W. H. Fitch, whose personal acquaintance I did not enjoy, has passed away one who, as a botanical artist, was long employed on Curtis' "Botanical Magazine." Many will miss the cheery countenance and pleasant words of Mr. John Matthews, the well-known manufacturer of garden pottery at Weston-super-Mare, although of late years increasing ill health has precluded him from joining in those meetings of horticulturists which he used to delight in attending.

In garden literature there has been no change, the weekly journals devoted to the calling keep on their way, and I think we of the JOURNAL may safely congratulate "our revered chief" on the continued vigour which has characterised it. Long may he

guide his vessel over the shoals and rocks that beset the course even of the peaceful and peace-loving Journal.

Such, then, is a brief sketch of the past season in its horticultural aspect as it has appeared to me, and now we look hopefully on. We cannot tell what the horticultural record of 1893 may be, any more than any other record of the future; but there is no diminution of the zeal with which the art is followed. Already we have the bugle call to make ready, and with the prospects held out to us in and about London it does not seem that there will be any falling off in interest.

I feel that it is not likely to be for long that I shall be able to perform the pleasant duty I have now fulfilled, and, therefore, let me with all good feeling wish you, my brothers and sisters, an old man's blessing in the opening year, and that amongst the many shifting scenes that lie before you, you may experience in your gardens as I have often done a happy enjoyment of God's works, leading you on to the thoughts of a better garden, which He has used to symbolise the pure and eternal blessedness of His kingdom.—D., Deal.

## "I WISH YOU A HAPPY NEW YEAR!"

### A POTATO-RAISING EXPERIENCE.

THE words above quoted greeted me several times this morning on my circuit as road surveyor, and as I repeat them in writing I wish them from my heart to our Editors and their readers. I have done so for many years, and it is nothing new, though it has never been a rule with me to rush into your pages without I think I have something new to say. Well, on January 5th, 1876, the well-known botanist from "the other side," Mr. C. G. Pringle, in a correspondence treating on hybridisation, wrote me from Charlotte, Vermont, U.S.A., "Besides the original species from the sides of the Andes, *Solanum tuberosum*, I cultivate one very distinct from our western territory of New Mexico, *S. Fendleri*. All my pains taken to impregnate it with pollen of the cultivated species has proved unavailing, though partially developed fruits have followed my operations, only to fall away, however, before maturity." On the following April Mr. Pringle sent me a tuber of his Snowflake, "and in a small tin box to go by sample post with this I send you three little tubers of *S. Fendleri*, which, though very small, are nearly of average size."

Probably Mr. Pringle sent me the wild Mexican (named after Fendler, the great traveller I presumed) to try my mettle, and it did, for both at Woodstock, and since here at Sulhamsted, till 1888 it defied all my pains to become impregnated with our cultivated sorts. In 1888 the pollen of my seedling Antagonist (now Sir Charles Douglas) came to the rescue. I had operated successfully with its pollen on some of Messrs. Suttons' wild varieties at their trial grounds, and upon several shy setters of my own seedlings effectually; then *S. Fendleri* became attacked as a forlorn hope—Antagonist's potent pollen conquered. In a few days after its application, to my great satisfaction, two berries began to show signs of swelling, and so on till one fell off prematurely; the other maintained itself till nearly ripe, and down it fell.

This precious production I conveyed at once from the seedling Potato trough, in the vinery *pro tem.*, to the missus's best glass cupboard for security (?), carefully placing it in a tumbler; and I must confess I forgot all about it, till soon after I found there had been a "cleaning up," and the "helper" had been set to dust out the glass cupboard and replace the glasses. "Dusting the glasses! Where's the Potato berry?" No one knew of it; no one had seen it. Well, the glasses were peeped into, the carpet retaken up, and the room reswept—no berry. *Exit omnes.* A very severe and early frost came, and turned all the tubers—of sorts precious that I had left undisturbed in the seedling trough—into pulp. Gone, *Fendleri*!

Four more years are gone, and then another up-to-date "cleaning" was being transacted in the past spring-time, in the midst of which my wife came rushing into the garden in hilarious pantomime, dancing a glass tumbler about in her hand, exclaiming, "Look here, father! Here is the Potato berry that Mrs. Woof lost!" Yes! Where did you find it?" "At the back corner of the cupboard." "Well, to be sure. Then we may say, 'all is not lost that is delayed.' So as you have had plenty of experience in manipulating the seed from the pulp you had better now try and dissect this dried up mummy, to find out if there is any seed within it that is likely to germinate." There were thirteen almost microscopic productions. Somebody's soap-box became filled with

drainage and fine soil; the seeds sown, and pieces of Rye Grass stalks as tallies, placed by each seed. Alas! in moving the box to a more convenient place, out went the bottom; and the contents lain all a sprawl on the vinery floor. I wish I could have had at command some wise proverb suitable for the occasion. . . . Suffice it to say, I had a shallow parallelogram box, erst used for raising Celery placed on the floor at hand. This I had got ready for Alice to sow with some choice flower seeds, so on to it at once I distributed the soil containing the precious Potato seeds. You may fancy I know a Potato's infantile appearance, and you can fancy how anxiously in this instance we watched for the appearance of these I am now writing about.

In due time three emerged for the light of day, but mysteriously disappeared in the night, as did others of them consecutively. A lanthorn and candle then discovered woodlice to be the cause. They had formed a lodgment at the bottom of the wooden box, and could not now be dislodged on account of disturbing the few remaining seeds which might be germinating. "The misfortunes of Nigel," and "The troubles of Werther," were out of the running; but I kept a strict watch now, and had the good fortune to secure two seedlings to become transplanted into small pots, as soon as I could perceive the cotyledons, and to be kept well out of the way of the depredators.

Of course the infants did not relish their being so early transplanted; in fact, one of them soon succumbed, and I believe so would the other had I not, as luck would have it, been showing to a friend the qualities pertaining to Tait & Buchanan's anti-blight powder, and the action of the Malbec bellows for its application. My friend said, "And what have you got here?" "Oh, the only Potato plant of its kind in existence, and that won't be for long by the look of it." I contemptuously gave it a puff of powder from the bellows as I said so, and from that time the little invalid revived into greenness, and grew away as much as it could until it ripened itself off. I conclude from this that the powder would prove a good antidote for sickly plants, and I feel sure all young foliage would be nourished by it, and the older foliage maintained in greenery. Chrysanthemums, &c., which are apt to become "leggy" would hold their foliage to the last, to the verge of the pot. But this in a parenthesis. Of course I summoned my wife to the digging, or rather the reversion of the pot, and behold the crop. The labour and the anxiety for which it has taken me, along with the above mishaps, seventeen years to accomplish—two ridiculously diminutive spherical white tubers about the size of small peas attached to the ends of abnormally long feelers, fine as the hair of one's head. What do you think of this, you raisers of Elephants, Giants, and Colosseans? Isn't it a "big thing" for England to have beaten America?—ROBT. FENN.

[Yes, and is it not a good thing when "helpers" clean out cupboards to look well into the corners? and does anti-blight contribute to the perennial greenery of our respected old friend and enable him to bear his Potato troubles so lightly? He is determined to be up to date, even in the missing word modernity. We have had a sight of the diminutive tubers, and we hope their triumphant raiser will in due time report progress with them—including accidents. This and the preceding article are written by our oldest correspondents— hale and active septuagenarians. A Happy New Year to them!]

### NEW RICHARDIAS.

A GREAT deal of what is being said and written in regard to the yellow and other "new" Richardias (Callas) is mere guesswork, or something worse. In horticulture, as in everything else, it is risky to jump to hasty conclusions, or, as the Yankees say, "to prophesy before you know." I am afraid "Boscobel" is one of the principal offenders in this respect. He began by stating that *R. Elliottiana* was a hybrid between *R. æthiopica* and *R. hastata*, and when asked for his authority said he guessed it. Then he produced the "unsolicited testimony of a careful and accurate observer and grower of a large collection (?) of these plants" to prove that his guess was correct. In the same communication he covertly admitted that *R. Elliottiana* comes true from seed. Now all this I shall venture to call the merest twaddle. Mr. N. E. Brown of Kew, who knows more about Aroideæ than any living botanist, says of *R. Elliottiana*, after having seen it at one of the exhibitions, that it is no doubt a distinct species. The fact that it comes true from seeds bears out this view, as no true hybrid reproduces itself from seeds. Had *R. Elliottiana* been a hybrid then "Boscobel's" expectation that "a large proportion of the seedlings may be expected to revert to one or other of the parents" would have been reasonable.

*R. aurata* is advertised with a great flourish of trumpets by a French nurseryman, M. Deleuil of Marseilles, who says he

a. R.

R.

R.

obtained it by crossing *R. albo-maculata* and *R. hastata*. He quotes the notices of *R. Elliottiana*, and then states that "un Anglais bien connu" who saw his hybrid in flower said it was identical with Captain Elliott's plant. I am told that this "well-known Englishman" is a young lady from Kensington. It is possible that M. Deleuil's plant is all that he says it is, but he is certainly unwarranted in declaring it to be the same as *R. Elliottiana* on the mere testimony of a young lady. I venture to advise would-be possessors of the yellow *Richardia Elliottii* to be careful of hasty conclusions, and to remember the consequences of "buying pigs in pokes." If M. Deleuil's plant is so good how is it that we never heard of it until he had a quantity of large tubers of it for sale? Has any known horticulturist seen it?

"Boscobel" thinks Deleuil's plant will probably turn out to be "either identical with *C. Elliottiana* or will closely resemble it." What has become of the belief that the latter was a hybrid between *R. hastata* and *R. africana* (*æthiopica*)? Then "Boscobel" attacks *R. Pentlandii*; he says, "undoubtedly its true and correct designation should be *C. æthiopica aurea*, as it is admitted by all who have seen it to be merely a very fine bright golden form of the type." Permit me to say that after having carefully examined *R. Pentlandii*, and ascertaining its history, I feel quite certain that it has nothing whatever to do with *R. africana* (*æthiopica*) beyond belonging to the same genus. I cannot understand how even "Boscobel" can be so venturesome as to say "that the plants recently sold by auction as 'Pride of the Congo' will prove to be what is known as *R. Pentlandiana*." I call this kind of jumping "flat burglary." Possibly such a guess may prove the correct card, but at present it is worth nothing to anyone except, perhaps, "Boscobel" and the vendor of "Pride of the Congo."

This is briefly how we stand with regard to the genus *Richardia*. There are five good properly described species in cultivation, namely—*R. africana*, spathes white; *R. albo-maculata*, spathes creamy white with a purplish blotch at the base, the leaves being spotted with white; *R. hastata*, spathes dull yellow with a blotch of crimson at the base, leaves unspotted; *R. melanoleuca*, spathes rather small, not folded trumpet-like, pale yellow, purple at the base, leaves spotted; this species differs from *R. albo-maculata* in having shorter leafstalks with a few setiferous hairs at the base. *R. Rehmanni* has small white spathes in form like those of *R. africana*, and lanceolate instead of hastate leaves. In addition to these we have the new ones, namely—*R. Elliottiana*, raised from seeds imported from Africa six years ago as "Red Arums." I am informed that the Kaffirs have only one word for red and yellow. If this is correct we have the seeming mistake explained. It was shown at a meeting of the R.H.S. in the spring of 1890 and again in 1891 and 1892. It reproduces itself from seeds. The plants were distributed by auction sale in June last. It has hastate spotted leaves and large clear yellow spathes.

*R. Pentlandii* was flowered this year by Mr. Whyte, who obtained it from a tuber presented to him along with five others. It is a very handsome plant, distinct from and superior to *R. Elliottiana*, equalling almost in stature and size of spathes the common *Arum Lily*. It differs from this species, however, in the texture of its leaves, in the colour of its spathes, and in its truly deciduous habit of growth, *R. africana* not being really deciduous. *R. aurata* I have already dealt with; its spathes have not been seen, except in M. Deleuil's nursery. "*Calla nilotica*" is advertised as having white and red spathes, and as having been collected on the banks of the Nile; and "Pride of the Congo" I suppose we are to believe comes from the region of the Congo. I know nothing of these two plants, and the only criticism I shall offer with regard to them is this. *Richardias* are all natives of South Africa; at any rate, no plants have yet been found north of the Transvaal. I therefore venture to doubt what the namer of these two plants would have us believe—i.e., that one is from the Congo, and the other from the Nile. The popular name for *R. africana*—viz., "Lily of the Nile"—is misleading, this species not occurring wild within 1000 miles or so of the Nile. It is a native of the Cape.

It is evident, I think, from what I have shown that some of us are a little mixed with regard to these plants.—W.

### TOMATOES AND MUSHROOMS.

I WAS very much interested in a communication which appeared in the Journal a few weeks ago (page 478, December 1st, 1892) from Mr. Buchanan, respecting "Tomatoes and Mushrooms." He said: "We took out two trenches 1 foot deep and 1 foot broad in the spring, spread in a small quantity of old Mushroom bed, planted the Tomatoes in rows in the usual way, giving round each plant a good dressing of the fertiliser, Thomson's manure. The result has been good crops of Tomatoes and as fine Mushrooms as ever were grown."

According to this statement, the border was spawned simply by using a small quantity of old Mushroom bed, no other manure being used

except the dressings referred to. Now I should like to know whether the insertion of the ordinary brick spawn would have an equally good if not better effect in producing Mushrooms, using, of course, Thomson's manure in the way Mr. B. recommends; because if so it would be a very useful way of raising Mushrooms without the agency of horse manure, which, with those who do not keep horses, is somewhat difficult to obtain of the right character for that purpose.

As Mr. Buchanan made his border up in spring, it would appear as if the spawn was somewhat slow in permeating the soil, as he did not begin to gather Mushrooms till August. I suppose this would be partly accounted for by the layer of old Mushroom bed being placed at the bottom of the trenches 1 foot deep. Moreover, the temperature of the border would, I presume, have something to do with retarding their appearance. Will Mr. Buchanan or other readers oblige with opinions and suggestions?—J. F. CRANSWICK.

### THE NATIONAL ROSE SOCIETY.

THE annual general meeting of the Society was well attended, and got through a good amount of business, one important reform being carried, and two others lost. It is, I take it, a healthy sign of vigorous life that these meetings are now occasions for debate and decision on important points as well as for mere matters of routine, and now that this is so, such a capable Chairman as Mr. Wilks was a distinct boon to the progress of business. The report speaks of the Crystal Palace Show as the largest the Society has ever held, and "E. M." and Mr. Grahame have told us in the Journal "what a success" it was. No doubt they are right if success depends entirely upon the number of classes and entries; but I should have thought smoothness of arrangement and quality of exhibits were also necessary elements in the making of a successful show; and, beside the generally lamented absence of fourth prizes, it seems to me that it would be possible to find something wanting in these particulars.

### SPACE FOR EXHIBITORS.

It is a busy time that two or three hours of setting up before judging; and if anyone is showing in several classes, with a good many large boxes requiring two persons to carry them (and thereby contributing, I suppose, to the success of the show), it is very difficult to arrange them unless he has all his boxes together in one of those charming side spots with which the Palace abounds. It is, moreover, very trying, when all at last is ready, to find there is no room to be had in those classes where entry has been duly made some days before. 1892 is not the first year that the boxes of myself and others have had to go on the floor, or be piled up somewhere where they could not be seen; and I would simply like to ask whether the management would not hear of it, if this was to occur at a small provincial show.

At my own little cottagers' vegetable show, I should be ashamed if the labourer who had paid his pence and made his entry had not room provided for his Potatoes and other produce; and when all entries are rigorously made several days beforehand, I cannot see what is the difficulty in providing sufficient space. I am told the C.P. authorities were to blame, and I make my grumble, hoping it will reach them, for there was certainly a want of "success" in this matter. I am getting too old to fight for a place myself, and, having lost my assistant, fear I shall have to drop out in favour of more vigorous members; but I should be very glad to see the N.R.S. set a good example instead of a bad one in this important respect to country shows.

The financial statement could hardly be called very flourishing, and the complaint of the Treasurer as to the difficulty of getting members to pay their subscriptions is much to be regretted. I think the recommendation of the Society that all members should as far as possible give orders to their bankers to make these payments should be more strongly urged and that this would have a good effect in punctuality and the saving of labour.

I much regret that it has been found impracticable to arrange for the holding of the Provincial Show in East Anglia. This portion of the kingdom has, on all accounts, a strong claim for consideration in the matter; but, alas! we have no money, and must go north, "where money is."

The important question of the date of the Metropolitan Show was again fully debated, and now that it is settled for the year it may not be desirable to reopen it at present. Perhaps I do not look upon the question impartially, but it seemed to me that the arguments of the opponents of Mr. Pemberton's motion consisted principally of "I should not be able to show at my best," while his supporters were so full of argument of all sorts that the time would not suffice for them. A notable division of opinion on the matter exists throughout the Society; opposite sides are taken by my neighbour, whose portrait

appeared on page 555, and myself, by Messrs. Grahame and Bateman, who, as leading "metropolitan members," might be expected to think alike, by the two Secretaries of the Society, and in one rosarian household by husband and wife!

The appointment of one Committee instead of two, with power to appoint sub-committees for special purposes, is a useful reform, and found general favour.

#### THE PROXY QUESTION.

The suggestion that members should be allowed to vote by proxy seemed so extremely reasonable that I was surprised at its rejection. I heard no argument whatever against it, except that it would be more trouble to the Secretaries, and I feel sure that with judicious management this might be reduced to a minimum. Either on this question, or that of the date, someone read from the list the comparatively small number of northern members, showing them to be very much in the minority. This was apparently meant to prove that their claims might be disregarded; but, apart from the question of the "rights of a minority," it might well have been argued that the number of northern members is so small *because* their privileges in the matter of voting at the general meeting and exhibiting at the National Show are so limited. I think that those who last year agitated with success for justice to small growers should have seen that northern members have not justice till they have the power of voting by proxy. Many thanks are due from rosarians at a distance to Mr. Grahame, who did see this and ably seconded the proposal, and I hope—for the motion will surely come on again till it does pass—that all other "metropolitan members," as those within easy reach of London may be called by way of distinction, will see before next year that justice calls for this reform, and that in the interests of the *National Rose Society* it is as desirable to give fair play to the members at a distance as it was to the small growers.

#### THE MEDAL HYBRID PERPETUAL ROSE.

I was unable to take a full view of the Show, but should have said, from the classes which I assisted in judging, that the standard was below the average, though not so low as it has been. A circumstance occurred, however, which reconciled me to not having seen a good many of the stands, and made me think the general standard of H.P.'s must be lower than it had ever been before. This was the selection of a certain Gustave Piganeau, in a box which I had been helping to judge, as the nurseryman's medal H.P.—a bloom which, though good (not extra) in other respects, had a distinctly split centre. On my remonstrating, the medal judge (wild horses shall not drag his name from me!) said it was a case of either that bloom or withholding the medal, and I advised, if that was so, the latter alternative, though I admit it was not my business. If that was the best Rose, according to the rules, the standard of nurserymen's H.P.'s must have been very low indeed. The task of picking out the four best Roses in a show of 7100 blooms must be a very arduous one, and it is satisfactory that Mr. Burnside's proposition (anticipated by Mr. Shanks), which will very much lessen this labour, and we may hope render it less open to detraction, was carried by a considerable majority. From an exhibitor's point of view, the selection of the medal Roses at the Crystal Palace Show is a matter of great importance. They represent the standards of excellence by which all judging should be measured; and we all welcome any help towards making the choice as accurate as possible.—W. R. RAILLEM.

#### NATIONAL ROSE SOCIETY—VOTE BY PROXY.

I AM inclined to join in Mr. Gall's regret, that Mr. Foster Melliar's proposal to allow voting by proxy (I presume at the general meeting) was negatived. As a general rule, no doubt, people ought to hear the discussion before they make up their minds. But I believe it is very doubtful whether many votes are influenced in this way in the highest of all assemblies of deliberation—the English House of Commons. It would probably lead to a more general interest in the proceedings of the Society. At the same time, the tendency of late years has been rather to disallow proxies. That epigram no longer applied to the House of Lords:—

"By proxy I pray, and by proxy I vote!"  
A graceless peer said to a churchman of note,  
Who answered, "My lord, then I'll venture to say  
You'll to heaven ascend in a similar way!"

—A. C.

#### DISCUSSION ON POTATOES.

APPLES have a good, but not too good, share of attention. Cannot we also have a discussion on the Pomme de Terre? Potatoes and Peas have ever had a fascination for me. They are my favourite vegetables to grow and to eat, and I am not very easily satisfied with them, for there are Potatoes and—Potatoes. A variety which I have grown for two seasons is my first favourite for the table, and it has been so very highly fancied by my family that many of the seed tubers have been sacrificed to our appetite. The variety I mean is Laxton's Reward. In an evil hour I dug up a few roots when the haulm was yet green, and we had the produce for dinner, and the consequence was no other Potato would suit, so I supplied them as long as I could, and have left myself a scanty supply for seed. It is not a white-fleshed Potato, but has a yellowish tinge. It is very floury, but does not break; medium sized, and nearly all the tubers of a size. It is a rather strong grower and good cropper. Those who appreciate a really high-class Potato will be pleased with

this. "Early Laxton" is a round dwarf-topped companion to Sharpe's Victor. They are very similar in haulm, and with meripened at the same time. No better Potatoes for early work could be grown, and they are especially suitable for frames, owing to their dwarf growth. Vilmorin's "Eiffel" turned out to be a heavy cropping midseason variety, with which I was well satisfied. Early Puritan is useful, and I think an improvement on Beauty of Hebron, and certainly more saleable on account of colour of the skin. Bedfordshire Hero is a remarkably heavy cropping kidney, and the quality is good. It is profitable to grow, for it can be dug before the disease appears, and there are no small tubers. The General is a late Potato, and takes a long time in ripening; is a strong grower and good cropper. It is a white floury Potato, and I should judge will be good for spring use, being close in the grain and heavy—two essentials for a keeping sort.—H. S. EASTY.

I TRIED some of the new Potatoes the other day. Her Majesty is a very heavy cropper, and good in quality; Lady Francis is exceptionally good, and a free cropper; Astonishment, a very heavy cropper, but very poor quality; Lady Fife, excellent both in quality and yield. I think "Jeanie Deans" is one of the best Potatoes sent out for many years; the quality is first-rate, and the crop was heavy. A large field of them in Lincolnshire was a sight to remember.—H. H.

#### PRICES OF APPLES—STRAWBERRIES.

I AM glad that we have at last found out (page 542 last volume) the price of the Domino Apples. At first stated at 6s. a bushel by "W. P. W." it fell in his next letter to 4s. 6d., and in the last it appears that this was the market price, and that after deducting expenses at about 1s. 3d. per bushel, the nett price home is only 3s. 3d. or about half the first statement of "W. P. W." From this price, of course, the cost of production and gathering must be deducted. As we agree that "my object in writing in the first place was simply in order that readers of your Journal should not be misled by seeing 6s. a bushel stated as the price of Apples when the average price home to the grower has been much less," I think your readers will admit that I have gained my object.

I am sorry that "W. P. W." has endeavoured to draw attention from the main issue in order to try to get the best of the argument by side winds, and that he should write in the style that he did in his last. Artificial heat may be very useful for greenhouses, but is not required for Apples nor for discussing their prices. What "W. P. W." lacks in argument he makes up in "wordiness," taking up nearly a page of your paper to get out of it neatly, and to cover up his retreating footsteps after again letting the price down.

Ridicule may be an easy way of turning the subject or of beclouding it, but it is hardly necessary to say that it is not argument, neither will it advance the price of Domino Apples. If so, "W. P. W." would be able to sell to advantage.

And now to turn to the side issues. I have not time to enter into the price of the other varieties at 6s. a bushel. If I did probably they would melt away like that of the Domino, for I know what the price of Apples has been in the principal markets, and it is not likely that a grower would market all his Apples in several varieties, especially if there was a large bulk of them at just the time when prices were highest.

As regards my expenditure of £1200 a year for labour and manure (which "W. P. W." exaggerates to £1500), of course I could drop the manure; but probably I may be allowed to know my own business best. My aim is to crop heavily, and this cannot be done without manuring heavily. I not only plant my trees, but crop the spaces between with Strawberries, Potatoes, and other things, and it is the Strawberries that have paid most of the outlay, not Apples.

I must decline to write any further on the subject of the price of Apples, as I think sufficient has been said, unless "W. P. W." has another reduction to make in the price of Domino. I must also thank the Editor for having permitted such a full correspondence.

To pass now to the subject of fruit tree planting. Though "W. P. W." assumes that I wish to deter others from entering the same business as myself, I may inform your readers that Strawberries have been my sheet-anchor. About a half-plant crop on half my ground produced in 1891 £750 worth of fruit. It is only fair to add that this year the produce off the same ground was only £250, and also that I often made 4s. a peck in distant markets when the price other growers received in the same markets was only 2s. 6d. per peck of 12 lbs. The expenses are heavy, as I indicated in my last.

The advice I would give intending planters is, that all sorts of hardy fruits should be planted; not merely Apples, for according to my experience all in turn are profitable, and in like manner there are gluts of all occasionally, and low prices. The latter is in consequence of the former, for as soon as one crop shows up better than the rest such is planted so extensively that in a few years there is a glut. Fortunately the consumption of fruit has increased and is still increasing. It should, however, be borne in mind that, taking one season with another, the planter of a few acres must not expect a very large income, while anyone who goes in for planting a large acreage will (notwithstanding "W. P. W." and his ridicule of capital) find he has tackled a "big job," both as regards the expense of planting fruit trees and bush fruits, and also in cultivating them till they come into full bearing. On the whole the Strawberry may be recommended as the fruit which requires the least expenditure for planting, and brings the quickest and largest

returns, and there is practically no competition on account of the perishable nature of the fruit.—WALTER KRUSE.

LIVING as I do in a purely agricultural district some distance from a town, and having some experience of growing and selling Apples, the few remarks I am going to make on this subject may be worth noting. I have abundant opportunities of judging the difference between good and bad varieties, also good and bad fruit. In my neighbourhood there are an abundance of local sorts, but very few of the modern good varieties. While the locals were selling at 2s. and 3s. per bushel, I was selling to the same dealers Lord Grosvenor and Warner's King at 6s. per bushel. Worcester Pearmain and Lady Sudeley fetched 7s. per bushel, and I could not get nearly enough for the demand. Later on Cox's Orange Pippin realised 10s. without any trouble. Altogether I have sold between 70 and 80 bushels of surplus fruit, including a goodly number of windfalls; the average for the whole being 5s. 5d. per bushel. Surely, now, this is a remunerative price, obtained purely by reason of two things—good varieties and superior fruit. One tree of Ecklinville, thirteen years planted, yielded 6 bushels, sold to a higgler for 30s. on the tree; he expected to make 1s. profit per bushel when taken to the neighbouring town. Why was such a price obtained? Simply on account of the sort being a superior one—good fruit will sell; bad will not.—A YORKSHIREMAN.

RELATIVE to what has been said on this subject, the fact remains that well-grown and well-marketed home-grown fruit will and does realise more than your Kentish correspondent obtains for his (pages 478 and 532, last volume). There may possibly be something wrong in the staple of his soil, as he appears to cultivate well. Many soils are too light for the production of first quality Apples. I have sold no Apples for less than 6s. a bushel from the trees. Ecklinvilles, New Hawthorndens, Stirling Castle, and Blenheims sold readily at those prices. Earlier gatherings, including Lord Grosvenor, were sold from 6s. 6d. to 7s. 6d.; Worcester Pearmain, 8s.; Cox's Orange Pippin, 9s. and 10s. a bushel. The soil is a clayey marl. The trees are from six to twelve years old, the branches very thinly disposed, and the crop was quite as heavy as it should be; if much heavier the fruit would have been smaller, and its market value perhaps 3s. or 4s. a bushel.—A SUSSEX GROWER.

#### MR. J. MCINDOE AND THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

MR. MCINDOE seems dissatisfied with the so-called high-handed rejection of his entries from the autumn Show of the Society at Edinburgh. Had the complaints been lodged in a proper manner with the managers of the Show, instead of his rushing to the Press, any reasonable complaint would have been entertained and the alleged grievance searched out and reported upon.—A. M., Bristol.

[Our correspondent sends his name and address, but as he has not consented to their publication a great deal of his matter, which contains a grave allegation, has been necessarily expunged.]

As Mr. McIndoe has initiated a discussion on this very important subject of refusing entries at Edinburgh himself, he cannot complain if readers of the *Journal of Horticulture* should ask whether there were other reasons for the refusal of the Committee of the R.C.H. Society than those Mr. McIndoe gives. I put this view of the case forward, not for one moment in the belief that Mr. McIndoe has not told all, but because the Committee, in refusing so distinguished a gardener and exhibitor a reply, rather implies in its action that there is another reason, but declines to state for fear of a libel action, or something of that sort. If the Committee have no other reason for declining Mr. McIndoe's entries than those which he has given they lead the world to assume that they have reasons which signify criminality. It is a case that demands the interposition of a court of law or some other court, and Mr. McIndoe ought to have legal right to force the Edinburgh Committee to state their reasons publicly. Mr. McIndoe's charges against the Committee, practically of neglect to check stealing of fruit at their shows, is one which that body must in all honesty openly and fairly meet. It is not only a severe reflection on the Committee, but also on the Edinburgh public. Happily, this sort of thing is rare in London, and I believe there is no executive but would be only too ready to co-operate with exhibitors in repressing it. It is high time the Edinburgh Committee made a public reply to Mr. McIndoe's charges.—D.

THE habit of pilfering at shows leads to much annoyance, and ought wherever it exists to be ruthlessly put down. In many instances, when a gardener procures prizes for his exhibits, the owner of the produce very naturally often requires to see it on his own table, otherwise to send away to friends. Then what is to be done when it has been stolen during the Exhibition? Anyone showing does not wish to be compelled to stay by the side of his exhibits all the time the show is open.—G. F., Trafalgar.

#### MANURING FRUIT TREES.

IN your issue of 8th ult. "W. P. W." wrote a long homily upon the folly of "old world" fruit growers and their antiquated methods of culture. I ventured on page 452 to ask your correspondent a definite question, and received a very indefinite answer. My inquiry related to

the actual cost of manuring certain trees, as recommended by "W. P. W.," to which he replied by kindly giving directions respecting the quantity of stimulants required for trees. Verily a crooked answer to a simple and straightforward question. So loose a way of writing does much harm, for it checks progress. What on earth is the good of talking airily about "timely top-dressings" just as if superphosphates, nitrates, and kainit dropped from the clouds like manna in the wilderness? Not only are the fertilisers he mentions expensive to buy, but they are heavy, therefore still more expensive to transport from the dealer's stores to any but a few favourably situated orchards. Consequently "W. P. W.'s" fencing with my plain practical question of cost considerably discounts the value of the lesson he seeks to inculcate.—B. D. K.

[The above letter has been placed in the hands of our correspondent for his reply, which is as follows:—"B. D. K." desired to know the "cost per tree of a dressing of kainit and superphosphate spread from the stem outwards and a light sprinkling of nitrate of soda to follow." I agree that "loose methods of writing check progress," and this is a case in point. I do not hesitate saying, and I speak before the world, that there is not a practical fruit grower in the kingdom who could give a categorical reply to a question so vague as the one quoted that would be worth printing. I therefore did the best I could, as precisely and concisely as possible, to give a reply that might be useful to "B. D. K." and others, by indicating the quantity of the manures named per square yard to trees that did not make sufficient growth. I had in view just what "D. B. K." points out as to variations in cost of transport of manures "from dealers' stores to orchards." How was I to know whether your correspondent resides near any such stores or ten or twenty miles from them, or from a railway station? Again, how was I to know whether his trees were large or small, whether the roots occupied an area as represented superficially by 3 or 4 square yards, as is the case with thousands, or of 20 to 40 square yards with thousands more?

I assumed that anyone knew, or could obtain from his nearest manure dealer, the exact cost per cwt. of the different manures delivered at the place required; then by noting the size of tree—the rooting area as indicated by the branch growth, he could easily arrive at the exact "cost per tree" to himself (not to others differently circumstanced) on the basis of the quantities named for application.

Then comes another important element in the case—indeed, a vital one in determining the "cost of manure per tree." If "B. D. K.'s" orchards are extensive and he desires to purchase what he wants by the ton direct from manure works, the cost home will be infinitely less than if he wishes to buy locally by the cwt., or even in 2 lb. canisters. How was anyone to know by reading his "simple question" whether the querist is a ton man, a cwt. man, or a canister man? If the latter, the "cost per tree" will be 50 per cent. more than under the ton rate.

Your correspondent goes on to object that the measures named are "expensive." Very well; knowing so much, he may be expected to know the exact cost to himself. If he will be so good as to state what they cost him, and also state the height of one of his trees as well as its diameter through the head—the spread of the branches—I will then with very much pleasure tell him the cost of manuring such tree on the rates of application advised—first, for trees that make moderate but not sufficient growth; second, for restoring old or nearly exhausted trees.

Relative to the costliness of the manures named, the two of mineral character are, with one exception (basic slag), the least costly of all. Nitrate of soda, considering its action and the small quantity required, is as cheap as any nitrogenous fertiliser that can be obtained. The proper and intelligent application of manures is an investment, and a profitable one, as all the best cultivators in fields, farms, gardens, and orchards know full well; but not one of these could answer what "B. D. K." calls first his "definite," then his "simple," and next his "straightforward" question.

He is entitled to his own description and I am entitled to mine—namely, the question is one of the vaguest that ever was printed; yet I made an honest attempt to show how your correspondent could acquire the information he appeared to desire. I am snubbed for my pains, but that does not matter in the least. I will conclude by asking "B. D. K." a question just as easy to answer categorically and correctly as was his question to me, and he will then perhaps appreciate the nature of his puzzle. My question is equally definite, simple, and straightforward as the one I had to deal with—How much will it cost to make John Smith a suit of clothes? Whether John is a boy (like a small tree) or a man (like a large tree), or whether he wants lightly dressing (summer) or heavily dressing (winter) is for my chastiser to determine. It is an "airy" question I know, as it must be to run parallel with that of "B. D. K.," which may be fairly rendered, "How much will it cost to manure a tree?"—W. P. W.

#### MAINDIFF COURT.

THIS, the residence of the late Crawshaw Bailey, Esq., is situated about one mile from the town of Abergavenny. The view from the terraces on two sides of the mansion is magnificent. Far away stretch the peaks of lofty mountains, rising one above another, while below lies the pretty town of Abergavenny. The sides of a serpentine drive approaching the mansion are planted with Cedrus Deodara, which grow well considering the exposed position. The grounds and gardens are 21 acres in extent, and are laid out in a charming manner. Many beds are planted with hybrid and named Rhododendrons, all of which do well

and produce a wealth of bloom in their season. At intervals specimens of choice Conifers are planted, and these by annual top-dressing are kept in fine health. The shrubberies abound with all kinds of the choicest evergreen Conifera and flowering shrubs.

The Rose garden is close to the mansion, and the beds are planted with all the choicest varieties. Gladioli are also planted in the beds, these producing a good display when the Roses are past their best. Mignonette is grown round the single standard Roses. The flower garden is on the west side of the mansion, and during the summer is planted with choice bedding plants, which produce a charming effect.

The conservatory adjoins the house, and is a large roomy structure. Inside I noticed some grand specimens of Azaleas in variety 6 feet through, and a mass of bloom. Huge Palms, including *Latania borbonica*, *Seaforthia elegans*, and *Phoenix* in variety were also noticeable, likewise *Aralia Chabrieri* and *Araucaria excelsa* in good health. There are many fine Camellias, *Dracenas* in variety, and *Callas* grandly flowered. The side stages are filled with useful flowering and ornamental plants, and near the east end is a neat alcove covered with *Ficus repens* and Ferns dotted here and there with a fountain in the centre.

Leaving the conservatory I came to the Plum, Peach and Apricot, and Cherry case, 75 yards long. In this are some good trees of Black Tartarian and Governor Wood Cherries; *Victoria*, *Humboldt*, *Improved Downton*, and *Pitmaston Orange Nectarines*, with *Bellegarde* and *Alexander Peaches*. Entering the kitchen garden I first noticed a span-roofed range running north and south. This is divided into two divisions with side beds and a walk in the centre. In the first house *Eastnor Castle* and *Blenheim Orange Melons* are grown during the summer on one side with Cucumbers on the other. The extension system of Melon growing is adopted; and useful plants of *Mignonette* are grown in this house. In the next division *Roses* and *Pelargoniums* are grown and grandly flowered. The Early Peach house is a lean-to structure containing *Alexander* and *Hale's Early Peach* on the front trellis. The first named variety, I understand, does not drop its buds here; a cultural note on that from Mr. Harding would be of value. On the back wall there are *Lord Napier Nectarine* and *Lord Palmerston Peach*. The trees are in grand health and annually produce excellent crops of fruit. The next house is the Early vinery, planted with *Black Hamburgh*, *Foster's Seedling*, and *Madresfield Court Grapes*. The foliage is leathery, of good colour, and by strict attention to the roots grand bunches of Grapes are produced. I have seen *Black Hamburgh* here weighing 6½ lbs. and of a good colour.

I next entered a large span-roofed house with side and centre stages, on which are grown many kinds of stove plants, including *Pandanus*, *Crotons*, *Dracenas*, *Coleus*, and Ferns, with *Caladiums*, *Gloxinias*, and a large quantity of *Asparagus plumosus* for cutting. We pass on into the late vinery, which is planted with *Lady Downe's*, *Barbarossa*, *Alicante*, and *Muscat*. Next is a lean-to Pine house containing *Pines* in grand health. *Queens* are the favourites, but other sorts are also grown. Trophy Tomatoes in pots are trained as single cordons on the back wall, and produce a grand supply of fruit. Strawberries are also grown here on shelves. We next come to a long span-roofed house with side beds and walk down the centre, filled with healthy looking *Pines*, showing some grand fruits.

From this my guide takes me to a lean-to range in two divisions for growing late *Peaches* and *Nectarines*. These structures are fitted with shelves for successional Strawberries. About 700 Strawberries are forced, the varieties being *Hericart de Thury*, *Noble*, *James Veitch*, *Marshal McMahon*, and *President*. The first house was planted in the front with *Prince of Wales* and *Barrington Peaches*, and on the back with *Lord Napier* and *Pitmaston Orange Nectarine*. In the other house in front *Royal George* and *Grosse Mignonne Peaches* were planted, and on the back wall *Lord Napier* and *Stanwick Elruge Nectarines*. I have yearly seen splendid crops of fruit in these houses, some of *Prince of Wales Peaches* as much as 11 inches in circumference.

In the frame ground close by early *Potatoes*, *Cauliflowers*, *Lettuce*, and *Radishes* are grown in their respective seasons; also *Chrysanthemums* in all the best varieties. Here also is a three-quarter span-roofed house in two divisions, used for Cucumbers and Melons. *Hero of Lockinge* filled one house at the time of my visit, and a good crop of fruit was swelling. The other division was filled with *Cardiff Castle Cucumber*, which is thought highly of here for winter use.

The Mushroom house is a grand sight, having fifteen beds in it; also convenience for growing *Rhubarb* and *Seakale*. The west walls inside the kitchen garden are planted with *Apricots*, and north ones *Morello Cherries*; while choice *Plums* are grown on east walls, with a glass cover to protect the bloom. Those facing south are planted with dessert *Pears* in great variety, and in all the best sorts. Lifting the roots and an annual top-dressing are thoroughly practised here. I saw some *Pitmaston Duchess Pears* 1 lb. 7 ozs. in weight here, taken from trees lifted the previous year.

Herbaceous plants in great variety occupy the south and west borders of the fruit trees. *Currants* and *Gooseberries* are grown on the north borders, and the inner kitchen garden is divided into four squares, with walls between, and pyramid *Apple* and other fruit trees planted at intervals. These are kept root-pruned, and good annual crops are procured. Amongst other things I noticed *Model* and *Sutton's Queen Broccoli* in good breadths. The "Gentleman" *Potato* is thought very highly of here, one whole quarter of the kitchen garden being given up to the cultivation of it. This variety has a good future before it if kept true. The kitchen garden crops here are of excellent quality, and well repay for the system of annually trenching a portion of the ground for

vegetables. All the departments in these gardens are kept in good order, and reflects the highest praise on Mr. G. Harding, the able gardener.—C. J. S.

#### MR. N. SHERWOOD.

IN commemoration of the jubilee year of the great firm of Messrs. Hurst & Son, wholesale seed merchants, beautiful photographs of the founders and proprietors of the firm have been issued, together with those of members of the staff of the establishment.

We are told that the house was founded in 1843 by Messrs. Wm. Hurst and W. G. McMullen, who for many years represented the well-known seed firm of Warner & Co. of Cornhill, London (long since extinct). These gentlemen commenced business at 6, Leadenhall Street, on a very small scale; both, however, being well known throughout the country, and very greatly respected, the business grew fast, and rapidly became important. After some twenty years Mr. McMullen retired from the firm in consequence of ill-health, and Mr. Hurst took his son William into partnership. The style of the firm was then altered to

FIG. 1.—MR. N. SHERWOOD.

Hurst & Son. Mr. Hurst, sen., died in 1868. The business then devolved on his son and Mr. Sherwood, who married the youngest daughter of Mr. Hurst, sen., and with Mr. Johnson as manager, it was carried on until the retirement of the latter in 1890. Since that time Mr. Sherwood has assumed the entire management, and is now sole proprietor.

We reproduce the portrait of Mr. Sherwood, whose name has become familiar to most readers of horticultural literature through his connection with our gardening charities and the United Horticultural Benefit and Provident Society. He supports these Institutions by his genial presence at the annual meetings and by generous donations. He is the founder of the convalescent fund in connection with the Society last named, and the members, with a host of friends, will be pleased to see his portrait in the *Journal of Horticulture*.

AGRICULTURAL CO-OPERATION.—The twenty-fifth Annual Report of the Council of the Agricultural and Horticultural Association has just been issued to the members. The number of new members joining the Association during the past year has been 178. The total number of members now exceeds 3000, besides 500 co-operative societies supplied with seeds, manures, &c. The sales for the year show an increase of £3,873 4s. 2d., the total having reached £86,326 14s. 11d. In addition to strengthening the Association by writing off a sum of £933 15s. 9d. from last year's profits, a further sum of £2,223 16s. 11d. has been written off plant, &c., by way of depreciations, and £349 13s. 8d. has been added to reserves during the year. The customers of the Association have received £1,961, the employees a liberal share of profit, and there remains an undivided balance of £969, or £36 more than in 1891. As regards details of the business, the Council make a generous acknowledgment of the assistance rendered by the workmen at their profit-sharing works at Deptford, and speak warmly of the good feeling existing there between employers and employed.

**EVENTS OF THE WEEK.**—Apart from the customary auction sales not much of horticultural interest will take place in the metropolis during the ensuing week. On Tuesday and Wednesday, January 10th and 11th, however, the stove and greenhouse plants at Blenheim Gardens will be sold by auction.

— **THE WEATHER IN LONDON.**—Frosty weather continues in the metropolis. Sunday opened fine and seasonable, similar weather continuing on Monday, but with a very keen wind at night. A slight fall of snow occurred on Tuesday, and towards evening it became a little milder. Severe frost, however, was apparent on Wednesday morning, and a dense fog prevailed. The lowest reading of the thermometer in Fleet Street was 24°, or 8° of frost. In the suburbs from 15° to 20° of frost have been registered, at Chiswick 22°.

— **THE WEATHER IN THE NORTH.**—Frost varying in intensity from 5° to 18° on the morning of the 2nd has marked the week ending 2nd inst. The days have generally been duller than those of the preceding. Saturday was an intensely bitter day, with cold E. wind. New Year's Day opened with 9° of frost and a fall of snow sufficient to whiten all around, but little more.—B. D., *S. Perthshire*.

— **DEATH OF PROFESSOR WESTWOOD.**—It is with great regret that we have to announce the death of Mr. J. O. Westwood, Professor of Natural History in the University of Oxford, who was for many years on the staff of this Journal, even from a very early period of its existence. Mr. Westwood was born at Sheffield in 1805, and was consequently eighty-seven years of age. He was distinguished as an entomologist, and his most important works were the "Introduction to the Modern Classification of Insects," published in 1836; "The Entomologist's Text Book," published in 1838; "British Butterflies and their Transformations," 1841; and "British Moths and their Transformations," both beautifully illustrated by his own hand. Professor Westwood was awarded by the Royal Society one of their great gold medals, and he was elected to fill the place of Humboldt as a corresponding member of the Entomological Society of Paris. Professor Westwood died at Oxford on the 2nd inst. at three o'clock.

— **PEAR DOYENNÉ DU COMICE.**—The excellent illustration (fig. 75, page 565, vol. xxv.), and the short but truthful description relative to the value of Doyenné du Comice as a Christmas Pear given by your correspondent, "C. D., *Yorks*," I can fully endorse. With us it is a good cropper alike in the orchard house and as an espalier. We have had some splendid fruit, weighing over a pound each, from trees in 10-inch pots, whilst many of those grown outdoors weighed over half a pound, and this in a very unfavourable season. Of its handsome appearance one cannot speak too highly, for when perfectly ripe it is of a beautiful golden colour, and the flavour, I consider, only surpassed by Marie Louise. This is the kind of Pear to find a ready sale. English fruit growers only want to make such varieties as this thoroughly known in the market. Packed tastefully in boxes they rival any of the French Pears in appearance, and are, if in good condition, far superior in flavour.—R. P. R.

— **WHITE PLUME CELERY.**—Various opinions have been expressed as to the merits, or demerits, of this distinct and attractive looking variety. All admit how quickly and easily it blanches, but many maintain the quality is not good, tender crispness being wanting. I cannot help thinking that this diversity of opinion is accounted for by the great difference in soils and treatment. This variety has certainly proved exceedingly useful with us this season, being ready for table much sooner than any other when grown under the same conditions, and the edible qualities of it have been considered quite satisfactory. Our soil is rather favourable for the production of crisp, clean Celery, being naturally of a sharp gritty nature, and having received heavy dressings of stable manure. This, together with the frequent dustings of soot given to the plants in showery weather, and copious supplies of water when needed, have doubtless brought out the good points it possesses. We shall certainly place great reliance upon the White Plume next year, and would advise those who have not yet given it a trial to do so.—H. D.

— **GARDENING APPOINTMENT.**—Mr. Andrew Duncan, late foreman at Netherby Hall, Langtown, Cumberland, has been appointed gardener to Mr. Schott, Penny Hill Park, Bagshot, Surrey.

— **CROYDON HORTICULTURAL SOCIETY.**—The annual Show of the above Society will be held on Wednesday, July 5th, 1893, in the grounds of Brickwood House, Croydon, kindly lent by J. W. Prince, Esq.

— **A NEW PATENT CALENDAR.**—Messrs. Fletcher, Russell and Co. (Limited) send us a new patent calendar for 1893. It is compact and useful, being fitted with detachable leaves for every day in the year.

— **DEATH OF MR. W. HEALE.**—We regret to announce the death of Mr. William Heale of the Nurseries, Calne and Chippenham, which took place recently at Easterton, Wilts. Mr. Heale was in his eighty-fourth year.

— **HER MAJESTY THE QUEEN** has forwarded to the Secretary of the Royal Agricultural Benevolent Institution, through Sir Henry Ponsonby, a cheque for 100 guineas. This makes Her Majesty's third donation to the Society, in addition to her annual subscription of £25.

— **JAPANESE PLANTS AT CHICAGO.**—An American contemporary states that on December 1st a fine collection of curiously trained plants was received at Chicago from the Botanic Gardens of the Imperial University, Tokio, Japan. The plants all bear marks of the peculiar methods of strangulation as practised by the Japanese. One *Thuya obtusa*, not more than 3 feet in height, with a trunk 6 inches in diameter, is considered to be over 100 years old. Another, a specimen of *Pinus parviflora*, 2½ feet high, is thought to be not less than seventy-five years old.

— **THE WORLD'S HORTICULTURAL PRESS.**—A correspondent of a foreign contemporary has totaled up the journals devoted to horticulture with the following result:—"There are thirty-six in Germany, sixteen in Austria, eight in Hungary, nine in Switzerland, eighteen in England, ten in France, eight in Belgium, six in Holland, three in Denmark, four in Sweden, three in Norway, ten in Italy, five in Russia, one each in Portugal and Spain, nineteen in the United States of America, one in Canada, two in Java, one in Japan, and one in Ceylon, which make a total of 162."

— **WEEKS' HORTICULTURAL POCKET-BOOK.**—We are reminded of another step onward in the career of time by the receipt of the leather pocket "wallet," which the great Chelsea firm distributes at the beginning of each year. It is substantial, compact, and useful. It contains tables of reference for gardeners, blank leaves for memoranda, pockets for stamps, letters, and bank notes, and is illustrated with ornamental and serviceable glass structures which the firm produce so well. We shall be glad if gardeners can fill the wallets well with notes of information and others crisp and crackling that are good companions to their possessors. Our compliments to Messrs. Weeks & Co., and best wishes for a prosperous year.

— **WOLVERHAMPTON GARDENERS' ASSOCIATION.**—At a meeting held at the Midland Café, Queen Square, Wolverhampton, an Association was formed for the purpose of promoting the science and practice of horticulture. The want of an institution of this kind has been long felt. Mr. G. A. Bishop, The Gardens, Wightwick Manor, was elected Chairman; Mr. R. Craigie, The Mount Gardens, Hon. Sec.; Mr. McPherson, Hon. Treasurer; and a good representative Committee was formed, with the Mayor of Wolverhampton, C. T. Mander, Esq., President, and most of the leading gentlemen of the neighbourhood, Vice-Presidents, the Institution should be a success in every way. The first meeting took place on Tuesday last, when a paper was read by Mr. Bishop.

— **PEACH YELLOWS.**—Is the disease known as "Peach yellows" contagious? This question was recently considered in America, and the following is the result:—"The disease is contagious, and may be conveyed by healthy-looking buds when these are taken from partly diseased trees. Only a small amount of infectious matter is necessary to produce the disease, provided it is in the form of living cells which can be induced to unite with the actively growing tissues of the inoculated tree. In some cases the disease has a period of incubation extending over two years, and the probabilities are that additional experiments will demonstrate in some cases a still longer period. Many hundred experiments have proved these conclusions to be correct. The life of inoculated trees varies from one and a half to four and a half years. In orchards the death of the entire tree occurs in from one to six years. In a majority of cases the disease is chronic, and some part of the tree may live for a long time."

— **DEVON AND EXETER HORTICULTURAL SOCIETY.**—We understand that the Shows of this Society for the ensuing year are to be held as follows:—Summer Exhibition, August 18th; autumn, November 10th. Both Shows will be held at Exeter.

— **ENGLISH GRAPES IN AMERICA.**—Some months ago we referred to the fact that English grown Grapes were being exported to America with satisfactory results. Now we learn from the *Garden and Forest* that Black Hamburgh Grapes grown in England were recently sold in New York at 10s. per pound.

— **FARRINGDON STREET MARKET TOLLS.**—It has been decided by the Markets Committee of the Corporation of London that the exaction of tolls for produce sold in Farringdon Street new market shall be suspended for a year from January 2nd.

— **POPPIES IN THE ARCTIC REGIONS.**—A botanist reports that in the northern part of Greenland the Arctic Poppy forms one of the most beautiful features in the floral scenery. The flowers grow in immense sheets, giving a golden character to the country, that would, it is said, scarcely be equalled by a large field of Buttercups or Dandelions. Pure white blossoms are not infrequent among the yellow ones.

— **THE MEDICINAL PROPERTIES OF CEREUS GRANDIFLORUS.**—An American paper states that an extract obtained from *Cereus grandiflorus* is considered by physicians as an almost infallible agent for heart disease, they claiming it to be superior either to *Digitalis* or *Belladonna*. Two hundred pounds of this plant were recently shipped from the mountain country of Mexico to a well-known manufacturing druggist of New York city.

— **RAINFALL AT CUCKFIELD, SUSSEX, DURING DECEMBER.**—The rainfall during the past month was 2.60 inches, being 0.14 below the average. The heaviest fall was 0.51 inch on the 1st; rain fell on twelve days. Total for the year 27.05 inches, which is 3.60 inches below the average. Maximum temperature 53° on 15th; minimum 26° on 26th and 30th; mean maximum 42.2°; mean minimum 30°; mean temperature 36.6°. Partial shade readings 2° below the average.

— **A LARGE TREE.**—The section from one of the big California Redwood trees, which the United States Government will exhibit in its building at the World's Fair, has arrived at the Fair grounds. Eleven freight cars were required to convey it across the continent. It measures 30 feet long by 23 feet in diameter. The section is hollowed out, and when placed on end, divided into two storeys and lighted, as it will be, it will form a rustic house large enough for a family to live in.

— **SULPHATE OF IRON FOR FRUIT TREES.**—A correspondent writes:—"Apropos of your reply regarding sulphate of iron for Apple trees on page 573, December 29th, the following extract from a foreign contemporary might be of interest:—'It used to be thought beneficial to put the cinders and iron scales from the blacksmith's shop around fruit trees. Now the Australian fruit growers are digging trenches around the tree, and turning in a solution of sulphate of iron, made by dissolving the sulphate in water. For a large tree the trench should be 5 or 6 feet from the trunk.'"

— **MESSRS. FOSTER & PEARSON'S SHEET ALMANACK.**—We are favoured with the roll of twelve sheets, one for each month, in which the days and dates of the year are set forth with admirable clearness. Each sheet is margined with brief seasonable reminders on gardening operations, and on each is also displayed some of the specialities of the firm that have proved so useful in many gardens; and if gardeners could have their way, and amateurs do what they wish, the great Notts firm would have what we hope and feel sure will be their experience—a prosperous year.

— **FIELD VOLES IN SCOTLAND.**—The Committee appointed by the Board of Agriculture to inquire into the plague of field voles in Scotland have declined for the present to recommend the adoption of the plan lately carried out in Thessaly by Prof. Loeffler, who claims to have got rid of voles in that district by feeding them with prepared bait containing the germs of mouse typhus. It is thought that Prof. Loeffler may not have attached sufficient weight to other causes which have doubtless operated to reduce the swarms of voles in Thessaly, such as the heavy rains which on the low ground would flood the holes and runs of the mice. The Chairman of the Committee, Sir Herbert Maxwell, and the Secretary, Mr. J. E. Harting, with the sanction of the Board of Agriculture and of the Treasury, are, says "Nature," about to proceed to Thessaly for the purpose of taking evidence there and reporting.

— **SILVER MEDAL ESSAY.**—We have the pleasure to announce that one of the silver medals of the *Journal of Horticulture* has been awarded to Mr. G. A. Bishop, gardener to S. T. Mander, Esq., B.A., Wightwick Manor, Wolverhampton, for an essay on "Manures and their Application." The essay will be published in our columns when space becomes available.

— **A NEW HORTICULTURAL INDUSTRY IN CALIFORNIA.**—There is a prospect that California may have a new horticultural industry. A Frenchman has discovered that the California Roses possess 20 per cent. more volatile oil than the French Roses. If so we may expect attar of Rose and Rose extracts from that State soon. Are English Roses less productive in this respect?

— **GARDEN SCHOLARSHIPS.**—This is the title of a small pamphlet issued from the Missouri Botanical Garden, U.S.A. It is the fourth announcement concerning garden pupils, and is published with a view to encourage young men to take greater interest in gardening. The pupils sit for an examination, and those who pass are regarded as apprentices in the above-mentioned botanical garden.

— **OUTDOOR ROSES AT CHRISTMAS.**—"Walking on Christmas Day from Hastings to Battle," writes a correspondent, "I saw several Roses in bloom on a small cottage, and in a wood close by were many Primroses in full flower. I was informed by a woodcutter that he had that morning seen a thrush sitting on three eggs." Surely a striking contrast to the weather experienced in London and the North at Christmas!

— **FROST IN STIRLINGSHIRE.**—For three days in the beginning of last week the frost here was most intense. The maximum and minimum were, 25th ult., 26°, 12.6°; 26th, 22°, 11°; 27th, 29.6°, 10.2°; a mean temperature for the seventy-two hours of 18.5°. After the 27th ult. it got rather milder, but yesterday and to-day (January 2nd) the frost has again set in more severe with a slight fall of snow. The mean maxima for the week 31.9°, and mean minima 19.2°.—G. McDougall, *Stirling*.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—A meeting of this Association was held at the Memorial Hall, Farringdon Street, on Tuesday, January 3rd, under the presidency of Mr. T. W. Sanders. Mr. J. B. Riding, Chingford, read a practical paper on "Gloxinias," which excited some interest amongst those present, a lengthy discussion following. Twelve new members were elected, and the Honorary Secretary, Mr. D. B. Crane, announced that an excellent syllabus for the ensuing year had been prepared.

— **HABITS OF BIRDS.**—Birds vary in their habits in various localities. I never have a Crocus, Hepatica, or a Primrose touched by the birds, while not much more than a mile away Hepaticas and Primroses are destroyed annually in one large garden. Sparrows build in the Roses on the front of my house and in a Hawthorn arch in my garden, but not even the yellow Crocus is touched. They sometimes pull a few flowers of *Saxifraga Wallacei* to mingle with their building materials, but it is plentiful enough, and I can spare the few blooms they take.—S. ARNOTT.

— **LECTURES ON MANURES.**—A course of a dozen lectures on the "Action of Manures" has been delivered at Aldbrough, Hull, by Dr. J. Clark, of the Yorkshire College, Leeds, under the auspices of the East Riding County Council. On Thursday, the 22nd ult., the lecture was devoted to the action of manures on garden vegetables. The lecturer dealt more particularly on the action of farmyard and artificial manures upon Peas, Beans, Cabbages, and their allies—Onions and Leeks. The lecture was illustrated by limelight, and there was an attendance of eighty-six. Mr. J. W. Fell acted as Honorary Secretary.

— **A BOOM IN BANANAS.**—We have no information on the subject from fruit merchants in this country, but in the Eastern States of the Union there is, says a daily contemporary, an outcry that the rapid development of the trade in Bananas is seriously hurting the Grape market—that is, for Grapes as fruit, and not for the wine vat. It is certainly now quite a familiar fruit in this country, whereas a very few years ago it was almost unknown; but it is still rather high in price to reach the masses of the people. An American paper alleges that during August and September the Bananas imported into the United States aggregate 70,000 tons. We should think that if such an importation to this country were possible Bananas would soon be as cheap as Oranges or Apples. They are said to be very sustaining, and are very portable.

— **REPORT OF THE WEATHER DURING DECEMBER, 1892, AT HAMELS PARK.**—The weather during the past month has been of a very changeable character, commencing with hard frost and some light falls of snow; then came a few days of very mild weather, to be again succeeded by hard frosts, which have continued up till the present time. On some mornings 21° of frost were registered on the ground here during the latter part of the month. Rain fell on eleven days during the past month. Maximum mean any twenty-four hours was 0·42 on the 1st; minimum mean any twenty-four hours, 0·01 on the 11th; total during the whole month, 1·73, against 3·46 of 1891.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

— **PRESERVING WHOLE TOMATOES.**—We have had inquiries for a method of preserving Tomatoes without the admixture of ingredients that would affect their flavour. An Aldershot correspondent has sent the following recipe to Mr. G. A. Sala's interesting journal. The method, it appears, is adopted in Malta. "A thick layer of *dry* salt is placed in the bottom of a packing case, in which the Tomatoes are embedded, leaving a space of an inch or two between each fruit. Salt and Tomatoes are placed in alternate layers until the box is full. It is kept in a dry place, and the fruit keep well, turning out with a very slightly wrinkled skin, otherwise as bright as when plucked from the plants. Ripe, but not overripe fruit should be selected." The only failure was through overripe fruit bursting, and it is also essential that the salt should be *dry*. The recipe is worth a trial.

— **A HEAVY CROP OF POTATOES.**—Writing recently to a local newspaper, Mr. G. Harris, gardener, Alnwick Castle, Northumberland, says:—"We had such a fine crop of several varieties of second early Potatoes in 1891 that I was curious to know how much per acre was produced. The result was over 15 tons. Again, in September, 1892, the crop was extra fine. The Potatoes were carefully weighed, and the result was over 19 tons per acre from several varieties, with scarcely any disease and very few small tubers. This was not an experiment, but the ordinary course of gardening. There had not been Potatoes grown in either of these divisions for several years previously. There is a large quantity of humus in the form of decayed stable manure, certainly not rich in itself, in the land. A quantity of wood ashes, soot, and a general artificial manure had been applied to the previous crop. A light dressing of lime was given in each case when the ground was trenched during the winter before planting, the soil left rough in ridges to be pulverised by the frost. The latter plan is not sufficiently acted upon by allottees. In the spring the land was levelled down (end of March), and the Potatoes planted in rows, 2 feet apart by 15 inches in the row, inserted about 4 to 6 inches with a dibbler. Long stalked Potatoes require more room than this. If we could grow 10 to 14 tons per acre more frequently over the country, we should be able to export instead of import."

— **FLAVOUR AND YELLOW FLESH IN FRUITS.**—Can anyone who is capable of elucidating this interesting point tell us what affinity there is between flavour and the yellow tint found in fruits and vegetables? It is true that there is very little indeed of yellow in Pears or Melons, but then relatively how comparatively little of flavour. On the other hand, the richest of flavour found in fruits is perhaps in Pine Apples and Apricots, the yellowest of fruits, or in golden Plums, especially those of the Gage section. But the yellow tint in alliance with flavour is perhaps most marked in Apples of all fruits, for the simple reason that the greater portion of these fruits are white fleshed, whilst the yellow fleshed sorts always show the finest flavour. The very same thing is found in Potatoes, for whilst the bulk are of white flesh, the most pleasing varieties when cooked are those which have yellow tinted flesh. Then, if we turn to Vegetable Marrows, we find the same thing evidenced, and there are for flavour none so good as the yellow flesh Squashes, although in these, as also in the case of Turnips, yellow is a tabooed colour. The golden or yellow Turnips of the garden section are much more highly flavoured than are the common white ones. It is even held that yellow Tomatoes are superior to red ones, but in that case the colour is not so pronounced, being chiefly skin deep. The Golden Muscat of Alexandria Grape still ranks amongst the highest flavoured of that fruit, while if yellow-skin Peaches are not regarded as of such high flavour as red ones, we find green fleshed Melons usually of higher flavour than are white or scarlet fleshed sorts. Naturally it is not possible to lay down any hard and fast rule in relation to flavour and colouration, but the many cases quoted serve to show that some connection between yellow flesh and flavour is apparently evident. Most certainly the richest and most luscious of fruits, the Pine Apple, is yellow throughout, and of stone fruits the yellow Apricot and Golden Gage Plum find no superiors.—A. D.

— **GLASS LABELS.**—I have used, writes Max Leichtlin in the *Garden and Forest*, in the boxes where I keep my rarest plants glass labels, with good results. They are made of milky glass, which is dipped in some acid to take off the gloss and thus produce a soft surface, which is very agreeable to write upon. The names traced with a hard pencil stand the weather well, and the labels look like porcelain and are perfectly clean. By rubbing with emery paper, sand, and water the writing can be perfectly effaced and the label used again. This form of label, however, has one great disadvantage, that is, a brittleness which makes it very liable to break.

— **SPRAYING APPLE TREES.**—The question as to the danger of poisoning resulting from the use of Paris green on fruit trees has been tested in Canada. At an experiment farm a peck of Apples was taken from a tree that had been sprayed twice with Paris green at the rate of 1 lb. to 200 gallons of water. They were gathered carefully, and analysed without rubbing or wiping. If there had been a fatal dose—2½ grains of arsenic in 23,000 bushels—they could have detected it, as they can find 1-50,000th part of a grain, but they failed to find even a trace of it in the peck. From this one may infer that with due care no injurious results are likely to accrue from its use, whilst a crop may often be spared if spraying is judiciously performed.

— **MESSRS. DOBBIE & CO.'S SOCIAL MEETING.**—In the Lesser Public Hall on the 30th ult. there assembled a company of about ninety, over which Mr. Wm. Cuthbertson presided. The occasion was the annual social meeting of the employes of Messrs. Dobbie & Co., seedsmen, and friends. The Chairman was supported by Mr. Robt. Fyfe, Bailie Burness, Mr. James Dobbie (founder of the firm), Mr. Andrew Mitchell (manager of the firm's seed farm at Beaulieu, Hants); Messrs. S. Jones and R. Smith, heads of departments at Rothesay, and others. Mr. Cuthbertson, in his opening address, said he believed the horticultural trade was on the eve of a very great development. There was a cry for fruit culture, small holdings, and allotments, and it might be the duty of the horticulturists to take from the land that successful result which the farmer had failed to secure. He concluded with a few words of compliment to Mr. Dobbie and the expression of the hope and belief that if all the employes and the heads of the firm continued to do their duty there was nothing but prosperity in store for them.

— **FERTILISERS AND SOILS.**—A series of investigations on soils is in progress at the Maryland Agricultural Experiment Station, in co-operation with the U.S. Department of Agriculture and the Johns Hopkins University. So far the work has been on the physical structure of the soil and its relation to the circulation of soil water, and the physical effect of fertilisers on soils as related to crop production. The surface tension of various solutions was first of all determined. The solutions chosen included common salt, kainit, superphosphate of lime, soil extract, and ammonia. The soil extract was made by shaking up a little soil with just sufficient water to cover it. The water was afterwards filtered off and used for the determination. This operation reduced the surface tension of water considerably, but the experiments do not appear sufficiently complete to indicate reasons for this. Analyses of the soils are not given. Ammonia and urine lowered the surface tension of water considerably below that of the soil extract, and still more below that of pure water. Common salt and kainit increase the surface tension of water, and no doubt, says "Nature," this is the reason why the application of these substances to the soil tends to keep it moist, whereas the excessive use of nitrogenous manure has the reverse effect.

### CAMELLIA SASANQUA.

No little interest was aroused at the last meeting of the Royal Horticultural Society by the exhibition of the Japanese Camellia Sasanqua by Messrs. J. Veitch & Sons, and a first-class certificate was awarded to it. The plant is not of quite recent introduction, having been sent to the Chelsea firm by Mr. Maries some fourteen years ago, but in all probability it was new to the majority of the visitors to the Drill Hall on the occasion referred to.

Camellia Sasanqua (vernacular name Sasank'wa) was first made known to science through Thunberg towards the end of the last century. It occurs wild in Kinsin, the southern island, and is cultivated farther north. The wild plant is an upright shrub from 5 to 10 feet high, flowering from December to February (Siebold).

At Coombe Wood Messrs. Veitch & Sons find C. Sasanqua much hardier than the ordinary Camellias, and it also sets its flower buds much more freely. This is a point that is well worth bearing in mind. It is worthy of trial as affording variety in a collection of climbers out

of doors, and although not tender it would be advisable to give it the advantage of a sheltered wall in order to encourage the ripening of the wood, the setting of the flower buds, and to protect the flowers from

brush of yellow stamens. A double white form, a variety from it, was also shown. *C. Sasanqua* might prove serviceable for hybridising, and a race uniting its qualities of hardiness and bud-retention with the beauty

FIG. 2.—CAMELLIA SASANQUA.

injury at the unsettled period of their development. The plants exhibited were bloomed in a cold house without any heat, and it will be noted that they were in flower at the middle of December. The type (fig. 2) is single, and has bright rosy pink flowers with a prominent

of bloom displayed by our choice varieties would be very valuable. The following references may be found useful by those desiring further information respecting it. Thunb., *Fl. Jap.*, p. 275; Sieb. et Zuc., *Fl. Jap.*, I., p. 158, t. 83; Franch et Sar., *Enum. Pl. Jap.*, I., p. 60.

## THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE members of the General Committee of this Society held a meeting at Anderson's Hotel, Fleet Street, on Friday evening last, to consider the report of the Schedule Sub-Committee, and transact other routine business. Mr. Rd. Ballantine occupied the chair.

Mr. R. Dean, in presenting the report, announced that the Dowager Duchess of Sutherland and Lady Saunders had consented to become patronesses of the Society, and that Sir Trevor Lawrence, Bart., President of the Royal Horticultural Society, Sir Hy. Peek, C. C. Paine, Esq., and Leopold de Rothschild, Esq., would be added to the list of Vice-Presidents. The Sub-Committee recommended that in future the Floral Committee consist of eighteen members, instead of fifteen as hitherto, one-third retiring annually, but being eligible for re-election. It was further recommended that the Chairman of the Floral Committee shall be annually elected by the General Committee at their first meeting after the Society's annual meeting, and that such Chairman be elected from the members of the Floral Committee. In the general regulations for exhibitions a few verbal alterations were recommended, the principal one being that the Arbitration Committee shall have power to reject any products not considered worthy of exhibition.

There will be no September Show held by the Society. This has been taken over by the Royal Aquarium authorities, but the N.C.S. will provide a sum of money to be offered for early flowering Chrysanthemums at that Show. Mr. G. Gordon and Mr. H. J. Jones will be the judges the Chrysanthemum classes; the other judges will be appointed by the Aquarium Society. An October Show will be held, as was the case last year; the judges appointed will be the same. At the great November Show Mr. J. Lyne and Mr. S. Gilbey were recommended as judges in classes for plants, and Mr. A. F. Barron for fruit and vegetables, in the place of Mr. G. T. Miles; all the others remain as before. On that occasion the Floral Committee will meet on the second day of the Show, instead of the first as heretofore. There will be an Exhibition of late flowering varieties in December, and the classes proposed were announced. Mr. J. Kipling and Mr. H. J. Jones were proposed as judges.

An addition to the special regulations will be made to the following effect:—All cups or wires for exhibiting Japanese blooms shall be limited to 3 inches in diameter, and no extra supports of any kind shall be allowed. The alterations proposed in the various classes are too numerous to be dealt with in detail, and readers must be referred to the document itself when published, which will be somewhat earlier in the new year than before.

A list of special prizes was read from Major Collis Browne, Mr. W. J. Godfrey of Exmouth, Mr. R. Owen, Mr. H. J. Jones, C. C. Paine, Esq. Mr. E. C. Jukes intimated his willingness to offer a silver-gilt medal, a silver medal, and a bronze medal as prizes, to be offered in a new class composed only of small flowering incurved varieties like those of the Rundle family.

After some little discussion the report was adopted.

A member inquired whether the Society had any rule by which another member guilty of irregular conduct could be expelled, and was answered in the negative. Mr. Addison thereupon stated he had drafted a rule to that effect, and intended to move its adoption at the annual meeting. Several inquiries were made as to when the annual meeting would be held, and the Secretary stated it would be announced in the gardening papers in due course.

I SHALL be glad if you will allow me to reply, as briefly as possible, to the letters from Mr. Chas. E. Pearson and Mr. Henry Havelock, which appeared on page 553 (December 22nd). Both correspondents condemn the preponderance of metropolitan growers and exhibitors on the General and Floral Committees of the N.C.S.

As I pointed out at the annual dinner of the Society, this, if true, is entirely the fault of the country growers. Each affiliated provincial society (of which there are now eighty-six) has the right to send a representative to the General Committee, and this right, if acted upon to any considerable extent, would place the country members in a large majority on the governing body. The representatives of affiliated societies are usually, I am sorry to say, "conspicuous by their absence." I, personally, do not believe that it is the slightest use to have on the Committee men who cannot or do not regularly attend its meetings; and I entirely fail to see how the stability of the N.C.S. would be increased by electing such. However, the country members have the matter in their own hands.

One-third of the General Committee (by whom the members of the Floral Committee are appointed) retire from office at the annual meeting, and the country growers can easily, if they choose to attend that meeting, secure the election of a fair proportion of men who do not reside in or near London. If they will not take the trouble to do this it is surely unreasonable to blame those who do take an active interest in the Society and regularly attend its meetings.

As regards the "Beauty of Exmouth" case, Mr. Henry Havelock will see from the report of the Committee meeting held on Monday evening, Dec. 19th, that the Committee have not "treated the charge with

indifference," but that, after investigation of the circumstances, they have found it impossible to deal with it effectively without laying themselves open to a charge of libel. The "Wells" case was also fully discussed, and a resolution passed with regard to it.

And now, as to the appointment of Judges. From personal experience I can unhesitatingly say that these are selected without the slightest regard to their place of residence, or to their connection with the N.C.S., and that personal fitness for the post is the only consideration which has any weight with the Committee. That several of the Judges appointed are members of the Floral or General Committee can hardly be avoided, since most of the leading authorities upon Chrysanthemum culture belong to one or other of those bodies.

Nor is the method of the N.C.S. in this matter different from those of the R.H.S. and other National Societies, yet your correspondent does not find fault with these. Whilst agreeing with him as to the inadvisability of appointing local judges for local shows, I cannot see that the cases are at all parallel, or that the objections to such a mode of procedure apply in the least to the question under discussion.—EDWARD C. JUKES.

THE action of the Committee of this Society in relation to two complaints, made by exhibitors of new Chrysanthemums for certificates, against members of the Society's Floral Committee is astonishingly inconsistent. In the first case, that of Mr. Godfrey's complaint, the Editor of the *Journal of Horticulture* is taunted with not having published Mr. Godfrey's letter, and thus being rendered liable to an action for libel. The Committee shelters itself behind the very same plea in refusing to publish the name of the member of the Floral Committee implicated. Then, the Committee is careful to express no opinion as to whether Mr. Godfrey's charges are true or false, beyond saying that they are "vague." What is the natural deduction? Why, that the Committee prefer not to have to make the inquiry Mr. Godfrey desired. The country will draw its own inferences. Then in the second case, the charges made against a member of the same body also (I do not say "another" member), the Committee admit that the charge is proved by giving to the offender a severe reprimand. If one charge be substantiated, what is the natural corollary but that the other is not groundless? But mark this; whilst the Committee reflect strongly and most unjustly upon the action of the Editor in refusing to publish Mr. Godfrey's letter, containing what they call a "vague" charge, they having before them a charge from another source which is found to be true, and of which the offender is found guilty, yet themselves refuse to publish the offender's name. How grossly inconsistent! Can anything said by critics which so severely reflects upon the Committee of the N.C.S. as their own action in this case? One thing is certain—whilst thus protecting offenders, most persons appear to know very well who is aimed at.—ALPHA.

I HAVE noticed in the *Journal of Horticulture* that a member was condemned at the N.C.S. meeting. Was that me do you know? By the *Gardeners' Chronicle* it certainly looks like it (see page 773). Surely honest truth ought not to be condemned, and I can prove that all I have said is true. I do not know what all the members of the N.C.S. Committee think, but I know what some of them, and also the outside public, think of the peculiar proceedings.

I certainly do think the Secretary of the N.C.S. ought to bring all letters before the Committee which are addressed to them. Had he done so in this case, and I received an apology, the affair would have ended, but to have a letter from an individual member of the Floral Committee of the N.C.S. telling me he will take steps to prevent me showing among them if his small account is not paid is intolerable. The letters I have received from various people do not condemn me for the steps I have taken; what could I have done otherwise? I do not believe in sitting down and being trampled upon, and I resent petty tyranny. I did not intend the matter should be smuggled over.

The photograph of the famous letter was exhibited at the Aquarium because my letter was not brought before the Committee. Mr. Dean, in acknowledging the receipt of my letter, said he did not think "it a matter for the Committee." He passed the letter to Mr. Ballantine, who told me in his reply that "the matter must be settled in the County Court, and not by the Committee of the N.C.S." Mr. Dean expressed his surprise (page 400, November 3rd, 1892) that Mr. Godfrey "did not address his complaint in the first instance to the Secretary of the Society." This is just what I did, with the above result, and I was driven to take strong measures to get my case considered on its merits by the Committee. Their decision is my justification; but they have not published the name of the member whose action they condemned, much as they cry out for the publication of a name in another case which seems to have been "investigated" and (so far) settled on the mere word of the defendant? Can a precedent be found for this method? I think it must be new.

I am very pleased to learn there are gentlemen making inquiries into the whole matter. I should be very sorry to see the N.C.S. suffer for just one individual, but suffer it must by such indiscretions as have been dragged to the light. Is a man who wrote such a letter as that referred to a fit and proper person to be on the Committee of a National Society? Men of known discretion and free from all trade bias are needed there if anywhere. What is the effect of one weak link in an otherwise strong chain?—W. WELLS.

[We shall be pleased to insert a characteristic letter from Mr. Henry Cannell in our next issue. We should like a fair argument on

both sides, temperately expressed, as in the able letter of Mr. Jukes. "Alpha" is severely logical, and Mr. Wells is entitled to his explanation and comments. We do not know whether he is the member who was condemned or not, as we have received no official information on the point. We have been asked by the officials to publish the name of an individual against whom charges were made and who was *not* condemned for them; the same officials refrain from publishing the name of a member whose action they *have* condemned.]

#### CHRYSANTHEMUM PIDSLEY'S FAVOURITE.

THIS Chrysanthemum was raised by Mr. W. K. Woodcock, but the rage for large exhibition flowers has kept it in the background. It is one of the most effective decorative plants for the conservatory, having a most peculiar colour which is difficult to describe. A deep reddish salmon will, however, give an idea of its colour. Its flowers are similar shape of William Stevens. My plants were grown naturally, but slightly disbudded, and they had about a hundred flowers on each plant in 9-inch pots.—J. L.

#### GOLDEN WEDDING CHRYSANTHEMUM.

THE arrangement of our controlling the European stock of this variety, as stated in the *Journal of Horticulture* a few weeks ago, and sent out by the well-known American firm of Messrs. Peter Henderson and Co., has been cancelled.—JOHN LAING & SONS.

#### CHRYSANTHEMUM JOHN LAMBERT.

WHETHER this variety is recognised or not in the N.C.S. catalogue, it certainly speaks favourably respecting it. I quote the following from the centenary edition:—"John Lambert, which originated as a sport from Lord Alcester, is similar in form to its parent, and of practically the same colour as Golden Queen, and is perhaps the best stock of that variety." With that sentence I fully agree, and if John Lambert is the best stock (and therefore an improvement), why not act fairly and give the raiser the credit of it? I have for the past two seasons grown Golden Queen, Emily Dale Improved, and John Lambert, to fairly test the merits of each, and I have no hesitation in saying that the latter variety is decidedly the best. The growth of the plant is more free; I have found it more constant, and the flower is of better build, and possessing more solidity than either of the others.

This is just what one would expect, it being a sport from Lord Alcester, which is without a doubt the most perfectly built incurved in cultivation. Being fully convinced of the superiority of John Lambert, and taking into consideration that it has been awarded a F.C.C. under that name, I should think it a very unfair proceeding were I to exhibit this variety under its proper name, to find some other person had erased it and substituted another.—F. HOPKINS, *The Chestnuts, Walton-on-Thames*.

THE N.C.S. have recognised John Lambert. In the first place the Floral Committee gave undressed blooms a first-class certificate as a distinct variety; then the Catalogue Committee two years back classed it as synonymous with Golden Queen of England and Improved Emily Dale, describing J. Lambert as perhaps the best stock of the type. I find some of our best exhibitors have thrown Golden Queen of England away, and kept J. Lambert as advised by "Lancastrian" last year in your paper. I had no intention of again raising this controversy, only I notice where Mr. Molyneux judges I find Golden Queen of England substituted for John Lambert. This is misleading to the public, and I do not find any other member of the N.C.S. acting in this way when judging at shows. I wish to ask Mr. Molyneux, as he seeks to shelter himself under the N.C.S. rules, if he, when judging at shows where the National Society's Catalogue is to be the guide, goes by its rules in preference to his own judgment?—JOHN LAMBERT, *Powis Castle*.

#### CHRYSANTHEMUM MRS. ALPHEUS HARDY.

ON page 532, last vol., I notice inquiries for successful culture of the above Chrysanthemum. Having been fairly successful with it this season, I venture to give my method of treatment. I would remind cultivators not to discard this variety too hastily, as many have already done. When its culture becomes better known it will be seen more frequently on the exhibition board than hitherto. Propagated and grown the same as the general stock, with the same soil and mode of potting, allowing it to form its own natural break, retaining three shoots and saving the crown buds when they show, and housing with the general collection would, according to my experience, only end in failure. When well grown I consider this one of the finest white Chrysanthemums extant. I have had blooms this season 7 inches in diameter and  $3\frac{1}{2}$  inches deep; but I find them very liable to damp, and do not keep good more than a week at the most. I have exhibited flowers on two occasions this season, but unfortunately they were much reduced in size through having being a trifle too early, and suffering with damp as well.

I would advise striking this variety about the middle of December. Insert the cuttings singly in thumb pots nearly half filled with small broken potsherds, using a compost of peat, leaf soil, and sand in equal parts, well mixed. Put a little sand for the base of the cutting to rest on when inserting. Do not water if the soil is in a moderately moist condition (as it should be) but give a light sprinkle with a fine rose can, as the cuttings strike better than if watered too much. When rooted, do not be in too great a hurry to shift into larger pots, but keep them in a temperature of 45° to 50° near the glass. The cuttings must on no account be placed in cold frames. About the end of February shift into small 60's, using the same compost as for striking, adding a

little pounded charcoal, well draining the pots and potting rather lightly. At the same time place a small stake to each plant, as the stems are very very brittle, and must be kept well tied up all through the season. When recovered from potting place on a shelf in the greenhouse near the glass. Be careful with the watering, as the plants are very impatient of too much water at the roots in all stages of growth.

About the first week in April the plants will require shifting into 48 pots, using two parts fibrous peat, one part light fibrous loam, one part leaf soil partly decayed, with some pounded lime rubbish, charcoal, and sand well mixed. Pot a little firmer than before, but very firm potting must not be practised, as it is a feeble rooting variety. Provide good drainage; a light position on the front stages of the greenhouse near the glass will now be found suitable, as the shelves during April are too hot and dry for Chrysanthemums. As soon as the roots have taken hold of the new soil take out the tips of the shoots, and immediately they break rub all away except the strongest one and encourage this to grow, as it is from this growth that the flower will be produced. As soon as the plants require shifting into larger pots, which will be about the middle of May, they may receive their final potting, three plants going into a 12-inch pot, which should be nearly half full of carefully placed drainage, covering this with a little rough fibrous peat. The compost for this potting should consist of two parts fibrous peat, two parts light fibrous loam, one part half-decayed leaf soil, some charcoal, broken lime rubbish, and sand well mixed; no manure must be added to the compost. Work the soil well between the plants with the hands moderately firm, finishing off evenly on the surface; do not use the potting stick, firming with the hands is quite sufficient. Place a stake about 6 feet long to each plant. Be careful with the watering after potting. Still keep the plants in a greenhouse with plenty of light and air.

About the middle of July place them outside in a sheltered sunny position to ripen the wood. Give the plants support to prevent their being blown over by wind, and keep the shoots well tied. About the end of July or beginning of August the buds ought to show; these must be saved in all cases. Take the plants inside again about the end of August—into a light airy house with plenty of air night and day for a time, according to external conditions of the weather. No artificial stimulants must be applied to this variety, only a little weak soot water occasionally. If all goes on well the plants ought to be in flower and in good condition about November 6th. When showing colour they are best kept in a rather dry warm temperature, as they open a purer colour, and are not so liable to damp. Any attempt to keep the flowers in a low temperature after being taken from the warm house will end in failure, as they soon damp. They will keep far better on the plants in the warm dry atmosphere than cut and placed in bottles in cool places—at least this is my experience.

This was the first of the hirsute varieties sent out, and, as far I have seen it is still the best when in good form, and worthy of more extensive cultivation.—JAMES HAWKES, *Lillingstone House Gardens, Buckingham*.

#### PROFITABLE CHRYSANTHEMUM GROWING.

RESPECTING the amount of profit to be realised by the cultivation of the Chrysanthemum nothing definite can be stated, for that point greatly depends upon circumstances, which we are often reminded "alter cases." But it is obvious that the grower who is able to dispose of his cut blooms privately has a decided advantage over the ordinary market grower. The former has the field to himself and can to a great extent fix his own prices. In this way he supplies the public at first hand, and without the aid of an intermediate party. This increases the value of his produce, and from this point of view the Chrysanthemum is a promising and lucrative investment.

The market grower stands on very different ground. He can dispose of large quantities, but he has to take the prices that rule in the market, whether they are high or low. Good quality no doubt tells in the long run, but this fact is not always so apparent as it might be. Frequently he has to contend with glutted markets, depression of trade from bad weather, and numerous other causes, when the supply being far in excess of the demand superior blooms have to be sacrificed at a very low figure. The reverse of this is sometimes seen, when a particular colour or variety is scarce, a high price can then be obtained for second-rate flowers.

It is no part of the market grower's business to supply cuttings and young plants, therefore the varieties in general use are comparatively few in number. It does not matter whether they are old favourites or recently introduced novelties, but their selection is the result of careful consideration. The leading features in market Chrysanthemums are colour, size, a vigorous habit of growth, and floriferousness. Preference is likewise given to those sorts that can be kept longest without losing colour or otherwise deteriorating.

The object in view is to secure a continual succession of flowers, so that as fast as certain varieties are disposed of others are opening ready to replace them. The Desgranges and earlier varieties are grown in quantity, and are often flowered before they need removal indoors. On them I need not dwell, so I pass to the commencement of the Chrysanthemum season proper, which I will fix about the middle of October.

Operations commence with Lady Selborne, James Salter, and Mons. W. Holmes, representing respectively effective shades of white, pink, and crimson. These are followed closely by La Triomphante. This comparatively new Chrysanthemum is an immense favourite with market growers, judging by the way they have taken it up.

By this time a clearance of the early sorts has been made, and Source d'Or, Mdle. Lacroix, and Elaine come to the front. The two first

mentioned are very popular; but regarding Elaine I have heard expressions of disapproval from market men lately who complain that it cannot be kept for any length of time without showing its eye. This looks like rank treason, but several growers have freely expressed in my hearing their intention of growing it in less bulk, and replacing it to some extent by Madame Louis Leroy. I should think them likely to alter their views, for no Chrysanthemum secures better prices than Elaine, and if I were asked to name the premier market white, I should consider this variety's claims superior to all others.

After these the midseason varieties are in request to carry on the supply. They are somewhat numerous, and it will be sufficient to name some of the most popular. Amongst them can be seen Stanstead White, Sunflower, Mr. Geo. Rundle, Mons. Astorg, Fair Maid of Guernsey, Jardin des Plantes, Chevalier Domage, Cullingfordi, Victor Lemoine, and La Belle Jaune. A little later we find Madame C. Audiguier, Putney George, Lady Margaret, and Fleur de Marie. The last two, with La Marguerite, are in most demand among the Anemone-flowered section. Putney George is a good variety for selling, as the colour is very effective, and the shape and form somewhat unique. Cullingfordi is the most extensively grown crimson, and a market grower's collection can scarcely be said to be complete without it. The public taste would appear to be a little difficult to please in the matter of crimson Chrysanthemums. Probably the majority of buyers prefer shades of pink, yellow, or white, and nothing but a very superior form of crimson will tempt them. I have seen other varieties of this type tried, notably Edouard Audiguier and Mons. Bernard, but they failed to establish their position. The foregoing include most of the leading varieties in use by the market grower, excepting the late flowering ones. In thus indicating the principles which govern the market supply, I am aware that I have not compiled an entirely complete list. Nor is such a list possible, for individual taste and local considerations cause a wide divergence of opinion in selection and culture. Many growers show a preference for the incurved varieties, but the Japanese are the principal favourites. Before I leave this part of my subject I should add Avalanche, Peter the Great, Golden Thread, and Mrs. J. Wright.

Late Chrysanthemums secure good prices, and they are in brisk demand previous to Christmas. Ethel and its yellow sport Mrs. Jones are capital for furnishing a late supply. Princess Teck is also useful in this respect. The apricot-coloured Golden Gem, Mrs. C. Carey (white), and Hero of Stoke Newington (pink) are other good late sorts. To these may be added Meg Merrilies and its yellow sport Ralph Brocklebank. The two last named are generally grown, the one failing, as far as I can see, and which is common to both, being an extreme partiality to mildew. Singles are represented by Admiral Symonds and Pompons by Snowdrop and its yellow sport.

New varieties have generally ceased to be such by the time they reach the flower market. A market man near me grows Louis Boehmer and Ada Spaulding, but I think such is exceptional. If I were inclined to prophesy I should not find it difficult to predict that Beauty of Exmouth and Colonel Smith will eventually be utilised largely for the purpose under consideration.—ENFIELDIAN.

## DISCUSSION ON APPLES.

### TOO MANY VARIETIES.

"J. A. W." (page 500, last vol.) is right in saying there are too many varieties of Apples in cultivation, but has he not himself given too long a list of those "we really cannot do without?" Soil and situation are important factors in the question, and with many sorts it is difficult to say without trial whether they will suit the locality. It seems to be a good plan to try a variety of sorts at first. If good fruiting pyramids on Paradise are planted, and carefully attended to, two or three years will generally give a good idea of what will be the successful sorts to plant in larger quantities. It is a great pity to make a mistake and plant sorts which will not answer. Another point is this: With the present "boom" in Apple-planting, it seems likely that in a few years Apples will be very cheap up to January, and I prophesy that many persons will heartily wish they could change their October and November trees for others with the keeping powers of Bramley's Seedling, Lane's Prince Albert, or Wellington. It is the man who has a good Apple room still fairly stored with sound fruit in March who begins to feel paid for his labour and expense.

### DR. HARVEY.

The same correspondent is quite right as to Dr. Harvey. Throughout the large county of Suffolk it is one of the best known Apples, and for a non-keeper a very good one too. It is generally best to go in for the local Apple, as well as the local breed of cow or sheep in a district, not only because they are more ready of sale as better known, but also because it is generally a case of survival of the fittest, and the result of accumulated experience. We have just finished two or three sacks of Dr. Harvey to the satisfaction of all concerned; every fruit was good, of uniformly good size, and capital for all cooking purposes. The tree is easily distinguished at some distance, as it has often a semi-weeping habit, and in many cases a single fruit hangs on the end of a slender shoot almost like a golden ball of a pendulum. I wonder they are not more knocked about by wind than they are.—W. R. RAILLEM.

### A PLETHORA OF VARIETIES.

A MOST important subject has been opened up under the above heading, and I endorse most of the remarks of Mr. J. Watkins, page 533.

There appears to be an erroneous opinion as to the number of varieties of Apples that are grown for market in the United States and in Canada. I have heard it stated many times that only a few are grown, but in a list before me of Apples consigned to a large firm in Liverpool I find over sixty distinct varieties; and in another list, received a short time ago, over eighty varieties were named. This does not include many barrels marked as samples and unnamed.

Much has been said about our imitating American growers in marketing our Apples. The only thing I see worth copying is the care in grading. The fact that many barrels are described as "slack" or "slack and wet" indicate something wrong. No doubt the enormous importations of Apples lowers the value of home-grown produce; but it is an absolute fact that good home-grown Apples, honestly packed and properly graded, will realise more than the best American fruit from the market point of view.

I thought the collection of Apples staged by Mr. J. Watkins the most instructive and interesting in the Hereford Show. The twenty-five varieties were all suited for market in the majority of districts, and it would be very difficult to state which evoked the greatest interest—the market, culinary, dessert, or best flavoured dessert collection—each one having a group of specially interested people round it. This being the case, I fail to see how the increasing numbers of varieties are to be reduced. Personally, I would not plant more than half a dozen for market, but there are hundreds who plant Apple trees for their own pleasure or table, and they also like to test varieties for their own gratification. Again, some kinds of Apples which fail or are very inferior at one place, are just the reverse at another. As a case in point, the Northern Spy will scarcely grow or fruit here, yet it does well in other districts, as proved by some grand dishes of it at Earl's Court Exhibition. Lady Henniker is far from good here, but it is a splendid Apple in many places. I could name many others which behave in the same manner. I think it would be a great mistake to generally condemn any variety for the reason stated.—S. T. WRIGHT, *Glewston Court, Ross*.

### APPLE NORTHERN SPY.

THE fruits of the above which I exhibited at the Aquarium, and referred to by "A. D." (page 500, last vol.) were grown as he thought on an ordinary bush tree on the Paradise stock. The tree is growing in a very exposed situation, and the soil is a stiff cold clay. It has been planted twelve years, but like the trees of Blenheims planted at the same time had not produced a crop until this season. Providing the tree continues to bear it must be valuable for late use, as at the present time the fruits are as firm as when gathered. A friend who spent two years in Canada told me that it is one of the best sorts grown out there. American Mother, which is considered delicate and often advised to be grown in a warm situation, also does splendidly here in the above soil.—T. TURTON, *Maiden Erlegh, Reading*.

### THE COBHAM APPLE.

I HAVE been much interested the past few weeks to see that this grand Apple has not been forgotten among so many newer names, and it may be good sorts, to cultivate. Some years ago, it may be eight or ten, the name of Cobham must have become familiar to all readers of the Journal from my sending samples to the Editor to be named, the local name being "Improved Blenheim" and "Orange Blenheim" as distinguishing it from Blenheim Pippin, or Blenheim Orange. Since that time I find the variety is more commonly met with than was supposed by me at the time of writing, but that the crops are not distinguished by growers and dealers from "Blenheims," although undoubtedly a superior Apple. On reading the editorial reply to "J. T., *Fifeshire*," on page 495, I compared the description from the "Fruit Manual," and my crop this season (a poor one) and the Apples exactly corresponded.

I grafted some on a Hanwell Souring at about the time referred to, but the crop is not so fine flavoured or so saleable in appearance, partaking, I imagine, somewhat of the parent stock of the Souring, thus confirming in my opinion the interesting experiments made by Mr. Harrison Weir many years ago on the difference of stocks and the results obtained in the colour and flavour of the crops, a subject well worthy of studying and carrying out in these times of keen foreign competition. I met with a quantity of the true Cobham Apples in a fruit shop in this village some months ago, and I found they were being retailed at the low price of 2d. per lb., better fruit, I consider, than any American Apples I have seen there or at home.—J. HAM, *Astwood Bank, Worcester*.

### FROGMORE PROLIFIC.

I THINK that this Apple should not be allowed to fruit the first two years after planting. I planted five standards of this variety in November, 1881; the following autumn the young trees were loaded with fruit, and I left them all on "out of curiosity;" consequently the next year I had no fruit, and three out of the five died, while the two remaining ones had to be pruned back hard branch and root, lifted and replanted; three years were thus lost.—J. A. W.

### CELLINI.

THIS is an excellent and showy Apple, but, as "R. M., *Newbury*" (page 501, last vol.) writes, subject to canker on strong stiff land. All my standards on the Crab stock produced cracked fruit, but the pyramids on Paradise stock growing on the same soil produced splendid fruit without a sign of cracking.—J. A. W.

## NEW VARIETIES OF APPLES.

It is satisfactory to find that the Fruit Committee of the Royal Horticultural Society is exhibiting more than ordinary caution in the granting of certificates of merit to new Apples. In relation to a couple exhibited at a recent meeting, and found to be the best of the numerous seedlings submitted, it was agreed that the trees should be as it were interviewed by someone deputed by the Committee for that purpose. This is some satisfaction. It is very evident that there are very many Apples in the country, seedling or unnamed, the which are heavy croppers and passably good in quality, but yet are far behind our best named varieties. Still, those who have these unnamed sorts seem to assume, possibly through ignorance of what is really good in Apples, that they have some of superior excellence. When, however, these come before the Fruit Committee few indeed are regarded as meritorious. Only something exceptionally good can now hope to find a select place in the great roll of named and useful Apples.—D.

## QUORN HOUSE, LOUGHBOROUGH.

AMIDST the stillness and grandeur of the renowned forest of Charnwood, and only a few miles from the thriving little borough of Loughborough, may be found the historic village of Quorn, the home of the celebrated Quorn hounds, and situated in a central position in the parish is the delightful residence of W. E. J. B. Farnham, Esq., Quorn House. This is a singularly beautiful place, where gardening is most successfully practised in all departments. The grounds are beautifully undulated and well timbered. Standing near the lake in proximity to the mansion we appear to be far removed from every road, from every cultivated field, and from every village where the hum and stir of life may prevail, and the silence would indeed be oppressive but for the beauty about us. A clump of Cypress near by cut the sky with their feathery boughs, and their pointed tops had a golden smile upon them. We speak of the golden autumn as though all the leafage were of one colour, but in reality scarcely any two trees were alike. From the deepest russet to the palest gold, they presented themselves in that variety which is so charming. Amidst an avenue of Chestnut trees, one still lingers in the mind by its brilliant leafage, an ancient Oak, with limbs wonderful in their massiveness, and clothed from head to foot with golden leaves, and besides him his fellow, with form as massive, but with every leaf and acorn fallen upon the mossy surface beneath. In the distant forest glade, Oak after Oak, Beech after Beech, luminous and lovely, caught the eye, and stretches of tall silvery Birch appeared as a mist to complete the picture.

We turn with some reluctance from this delightful scene, and cross the wide expanse of well-kept lawn to the right and left of the mansion, each point being richly studded with fine examples of shrubs and deciduous trees of great rarity, and a noble carriage drive brings the visitor to the kitchen garden, with its colony of glass houses, in which many splendid examples of skilful culture are worthy of description. A well constructed span-roofed house, about 60 feet by 25 feet, is entirely devoted to the culture of *Nepenthes*, which bear every indication of careful culture, hundreds of well-pitched plants being suspended from the roof, evidently enjoying the humidity of the atmosphere produced by the ornamental tank, which extends along the entire length of the house. Amongst the most noticeable varieties are *Nepenthes Chelsoni*, *N. Findleyana*, *N. Hookeri*, *N. Rafflesiana*, *N. Mastersiana*, *N. robusta*, *N. Williamsi*, *N. Sedeni*, *N. sanguinea*, *N. Veitchi*, *N. coccinea*, and *N. hybrida*, each heavily laden with robust pitchers. The tank is planted with several varieties of *Nymphaea*, very noticeable being *Nymphaea odorata* and *N. dentata*, with their lovely sweet-scented blossoms floating upon the surface of the waters. An ornamental fernery occupies the extreme end of the house, from which a constant flow of water is obtainable, and is constantly dripping amongst the Ferns.

From this house we enter a long range of fine structures devoted to the famed collections of Orchids. The first division is occupied with some well grown *Odontoglossums* in various sizes. Many of the plants were throwing up strong flower spikes, and some fine varieties of *Odontoglossum Rossi majus* were in flower. A noticeable feature is that the side stages are thickly coated with sphagnum, in which the smaller plants are plunged. In the next division of this range are the *Cattleyas*. Many of the varieties are now showing their flower stems, and much beauty is promised. On the side stages were some highly coloured varieties of the beautiful *Cattleya aurea* and *C. Mendeli*. It is in this house where that magnificent plant of *Cattleya alba* (Quorn variety) which was recently certificated by the R.H.S. is grown, it apparently being in the best of health. We are next led into the *Dendrobium* house, in which there are many specimens in a high state of cultivation, the varieties being far too numerous to describe in an article of this description, but it is worthy of notice that the specimens of *Dendrobium Wardianum* are remarkable for their immense growth, in many instances measuring over 5 feet in length, the earliest now showing immense numbers of flowers. Other houses are devoted to the culture of Orchids. One house contains a large number of *Calanthes* in fine order, another is required for *Cœlogyne*, *Vandas*, *Masdevallias*, *Cypripediums*, *Lælias*, *Oncidium*s, and the beautiful *Cypripedium Spicerianum*, all flowering freely, and some pretty examples of the curious *Peristeria elata* were in flower.

The vineries and Peach houses are numerous and well-built structures. In the late vineries there were hanging many splendid bunches of well-

finished Gros Colman, Gros Maroc, Lady Downe's, Black Alicante, and Muscat of Alexandria, all admirably finished, and the berries are an immense size. Peaches, Tomatoes, Melons, and all the good things necessary for the supply of a large establishment are well grown. Several useful span-roofed houses are devoted to a general collection of finely grown stove, greenhouse, and other plants in great variety. Mr. Cooke, the talented gardener and general manager of the entire estate, is to be congratulated on the efficient manner in which he has planned and carried out the many improvements that are visible on every hand.—J. H. WALKER.

## TOMATO LADY BIRD.

AS a visitor to the Royal Horticultural Society's meeting on October 18th, 1892, I was much interested in a dish of a Tomato named Lady Bird, shown by Mr. W. C. Leach, The Gardens, Albury Park, Guildford. To me it appeared an excellent late variety, and justly deserved the first-class certificate awarded it. The fruits exhibited were handsome in appearance, and were said to possess an excellent flavour. I am told, too, that the variety is a very free setter, producing heavy crops of fruit under favourable circumstances. No doubt this

FIG. 3.—TOMATO, LADY BIRD.

Tomato will be extensively grown if you brought it to the notice of your numerous readers.—W. G.

[We described this excellent variety in the *Journal of Horticulture* for October 20th as a promising "Tomato for the million." We have now pleasure in publishing an illustration of it (fig. 3). In Messrs. J. Veitch and Sons' seed catalogue for the current year the raiser describes it as "setting freely and producing large clusters of unique fruit of medium size, nearly round, quite smooth, flesh of great depth with very little seed, and of deep crimson colour."]

## CANKER ON FRUIT TREES—IRON IN SOILS.

ALTHOUGH the data given by Mr. Kruse, on page 564 last week, as to his soil, in which there is much canker on fruit trees, are very full, it is difficult to express a definite opinion as to the treatment necessary to remedy the defects. The analysis he gives must be an old one, for the Dr. Voelcker referred to has been dead many years; and under any circumstances it may be a false guide, as no chemist is capable of defining what proportion of the several constituents of a soil is soluble and in a condition to be assimilated by plants, therefore there may be deficiencies not appearing in the analysis; and since the date of this analysis, as Mr. Kruse informs us, the soil in question has had regular applications of manure (mostly from horse stables), and also yearly applications of chloride of sodium, and recently of nitrate of soda. However, on the face of the analysis there appears an insufficient supply of soda, potash, and phosphoric acid.

A wide impression prevails that too much of the oxide of iron may be the cause of canker, but the proportion in the soil in question is by no means large, as some of the most fertile soils of which analyses have been published contain more than 10 per cent. of that constituent,

generally in the form of the peroxide. If my memory serves me correctly the soil of the fertile orchards of Herefordshire has nearly as large a proportion, therefore it is scarcely probable that the presence of iron oxide is the cause of the mischief.

Iron in such a form as to be capable of assimilation by the plant is absolutely necessary for its growth, therefore it may be that the soluble sulphate may supply a deficiency. Dr. A. B. Griffiths in his treatise on manures (London, 1889) records a number of successful experiments in its use, and I strongly recommend Mr. Kruse to study his book. The "Aschen Analysen" of Dr. Emil Wolff (Berlin, 1871 and 1880) is the great storehouse of plant analysis, but much that is useful on the same subject may be found in "How Crops Grow," by S. W. Johnson (New York, 1880).

From the analysis contained in these books it appears that the Apple requires a large supply of lime and soda and a full proportion of phosphoric acid, potash, and magnesia; therefore, I can only advise that the land be dressed with a manure compounded of superphosphate, potash, magnesia, and gypsum. I should have added soda if the soil had not already been regularly supplied with that element, and I think that sulphate of iron at the rate of from half to one hundredweight per acre might be added with advantage.

The Apple trees in my own garden treated in a similar way have ceased to canker, the only signs now present of the disease being scars of old wounds. I believe canker to be a disease of mal-nutrition resulting from deficiency in the soil of what is required by the tree, and not from the presence of anything injurious to its growth.—E. TONKS.

#### HARDY FRUIT GARDEN.

**Winter Cleansing Fruit Trees.**—The importance of thoroughly cleansing the stems, branches, and surroundings of fruit trees during the winter months is often overlooked. There are many enemies of trees which can only be successfully extirpated during the dormant season, when greater efforts can be put forth and stronger remedies applied to effect their destruction. Therefore, where many of the worst and most persistent of these pests are only too glaringly apparent, now is the time to attempt an effectual and complete riddance. Washes, insecticides, and solutions of various kinds are great aids in freeing trees of many evils, and rightly applied, with the necessary patience and perseverance, they assist the cultivator to cleanse trees readily and expeditiously.

**American Blight.**—When trees are infested with this unsightly pest it is sometimes difficult to eradicate it. The white, cottony substance which conceals the insect gives, in badly infested cases in the course of time, a most obnoxious appearance to the trees. The bark becomes contorted, and there is an absence of that clean and healthy freshness which trees in vigour and fertility display. In such cases there is also the danger of the pest attacking the roots, which it often does with the same malignity with which it infests the branches and stems. To some it is known as American bug, but though it has a great resemblance to the mealy bug so troublesome to plants under glass, it is totally different to that insect, which belongs to the scale family, the American blight being really an aphid, and is known as the woolly aphid. The insects, when crushed, stain the fingers and their downy covering with a red or pink colour.

**Remedies.**—One of the best remedies for the above is the application of paraffin or petroleum. The least touch of this mineral oil means death to the insects. Its use, however, demands care, as it is not safe to apply it so freely that it runs down the stems to the roots. The best plan of using it is to procure a clean but stubby paint brush, and dip it in a vessel of the raw oil; shake the brush sufficiently, so that none of the oil drops quickly from the bristles; then work the brush into the crevices of the bark, and the insects will be destroyed. This is an easy and very effectual method of destroying the pest on slightly attacked trees. On larger trees, however, and those almost completely infested all over readier means must be adopted. In the first place dislodge as much of the aphid as possible with a garden engine. It is easily moved from the younger branches when a sufficient force of water can be delivered. This preliminary washing can then be followed by a petroleum emulsion, which is made by boiling a pound of softsoap in a gallon of water, then adding three more gallons of water and four wineglasses full of petroleum, thoroughly mixing the oil and softsoap solution with a force pump for several minutes. Distribute this solution over every part of infested trees, using it while the buds are dormant at a temperature of 120°. The stems and branches, which can be easily reached, may be well brushed with the solution; also the strongest roots if attacked, and their exposure can be effected by removing the soil for facilitating the operations.

**Scale.**—Apple and Pear trees are most frequently infested with this kind of insect. Scale may be exterminated by scraping the infested parts, and thoroughly scrubbing with a strong insecticide. Encasing the infested stems and branches in a coating of ice, by syringing the trees with water in frosty weather, is a means of freeing them of scale,

which leaves the branches along with the ice when the latter melts. The upper parts of trees if infested may be sprayed or syringed with the hot petroleum emulsion recommended for American blight, and the lower parts thoroughly brushed with the same emulsion. A strong solution of Gishurst compound may be used either with or without petroleum, and it will be found effectual in destroying both scale and American blight.

**Moss and Lichen.**—These are very troublesome in some districts, especially where the situations devoted to fruit culture are damp and wet, owing to atmospheric conditions or badly drained ground. Drainage helps their disappearance; but in the majority of cases it is necessary to destroy them by the application of some drastic remedy. Moss and lichen are not only themselves injurious to the trees but they harbour insects; therefore the sooner they are removed the better. Very rank infestations should first be partly cleared by scraping off the thickest portions. The trunk and main branches may be readily cleared by washing with hot lime or brushing them with brine. To coat the upper and smaller branches with limewash or to paint with brine is out of the question, but if infested with moss and lichen they must be cleansed by some means; and finely powdered newly slacked lime distributed over the trees is a good remedy. Choose for this operation damp or foggy weather, the branches then being thoroughly wet on all sides. Mounted on a ladder as high as necessary, it is easy, by a few removals, to effectually cover every branch with a thin coating of powdered lime, which will readily adhere to their moist surfaces. That falling to the ground acts beneficially, so there is not the slightest waste. Limewash strained sufficiently fine so that it will pass through a syringe is another method of coating branches out of reach, and may be adopted with advantage in cases where the other method is not applicable. The lime acting on the moss and lichen growths will soon destroy their vitality, and repeated cleansings of the wood with a good force of water from a hose-pipe will restore the trees to their original healthy vigour and fertility.

**Aphides.**—Every fruit grower knows how troublesome these insects are in summer to Peaches, Nectarines, Apricots, Plums, and Cherries, especially on walls. Though not apparent now on the trees, it is possible that colonies of eggs are lurking in crevices of old bark, among the folds of dilapidated nail shreds, and in holes and crannies of the brickwork of badly pointed walls. As the pruning operations are duly completed, and all useless wood removed, it is advisable to thoroughly wash the walls with hot water, soap, and petroleum mixture, and to syringe every part of each tree with the same. If it is found necessary to be more precise and careful in cleansing the wood, then paint the trees with a brush, adding to the solution a little sulphur, which will help to indicate the progress of the operation by colouring the wood. Sulphur is also good as a deterrent of insects. In painting the wood operate upwards, so as to avoid the possibility of damaging valuable buds. Remove all old shreds and ties. Have the walls repointed where found necessary, and carefully refasten the trees with fresh material, using something of a strong enduring nature for the main branches.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest House.*—The trees started at the beginning of December are now in flower, and if in proper condition there will be no difficulty in securing a good set of fruit. The temperature should be steadily maintained at 50° by day in dull, cold weather, 55° when mild but dull with a gentle circulation of air, increasing the ventilation with the sun heat to 65°. On mild nights the temperature may be 45° to 50°, with a little air, but it may fall to 40° on cold nights. Avoid damping in very cold sunless weather, as a moderate moisture suffices. In bright weather the floor or border may be sprinkled in the morning, also early afternoon, and the soil should be thoroughly moist. Insure the distribution of the pollen by shaking the trees after the house has been ventilated a short time. A camel's-hair brush or a feather, or a rabbit's tail mounted on a small stick and drawn over the blossom when the pollen on the anthers is ripe and applied to the stigma of each flower, always secures a good set in perfect flowers. Where there is a deficiency of pollen take it from those varieties that afford it plentifully, as the Early Albert or its race, Early Louise and Early Leopold, also Royal George and Stirling Castle Peaches; of Nectarines, Elruge always supplies abundance of pollen. Carefully impregnate the blossoms when they are fully expanded.

*Second House.*—If this house contains trees of Alexander and Early Louise Peaches and Advance Nectarine, the fruit will be ripe early in May; if Hale's Early, Stirling Castle, or Royal George Peaches, and Lord Napier Nectarine, the fruit will not be ripe until the end of that month, while Elruge Nectarine will not ripen until the middle of June. Hale's Early is not a good setter early forced, but pollen can be taken from Stirling Castle or Royal George, and Elruge serves the same purpose to Lord Napier. A succession of fruit can be had over two months by having all the varieties in one house, but it is not a good system, it being better to have two houses, one with the first named, Alexander and Early Louise Peaches and Advance Nectarine, the other containing the last mentioned, Hale's Early, Stirling Castle, or Royal Peaches, the last having the finest fruit, Lord Napier and Elruge Nectarines, and start both houses together. The house having been closed, as advised in a former calendar, fire heat may be used to maintain a temperature of 50° by day, and 40° to 45° at night, allowing it to rise to 65° by day with sun heat, accompanied from 50° with plenty of air, and there must not be any attempt at husbanding the sun heat at this stage, for a close atmosphere is fatal to the blossom. Sprinkle the trees on fine days in the morning and afternoon until the flowers

commence to open, when the sprinkling of the floor in the place of the trees will be sufficient. The inside borders must be rendered thoroughly moist by repeated waterings. This applies to houses with fixed roofs, for, where the trees have been exposed, the borders will have been so moistened by the rains as not to require watering until the foliage and fruit are well advanced in growth. If the roots are partly outside, that part of the border should be covered with leaves and litter, so as to keep the roots in a condition to absorb and transmit nourishment, which they cannot do when the soil is frozen.

**FIGS.—Early Forced Trees in Pots.**—Those started in November or early December will need the temperature raised gradually to 60° at night, but 5° less in severe weather, and 65° by day from fire heat when the growths are developing, with 70° to 75° from sun heat, commencing to ventilate at 70°, and closing at 75°. Avoid, however, a high temperature by artificial means, as the sturdier and shorter jointed the young shoots and the stouter the leaves can be kept the greater will be the chances of a satisfactory first and second crop. Syringe the trees twice a day, except in dull weather, when damping in the morning and early in the afternoon will be sufficient, or less moisture will be needed where the fermenting material aids in furnishing heat than where reliance is placed solely on fire heat, and avoid a saturated atmosphere in dull weather. As the fermenting materials settle firm them well about the pots, and add more, taking care that the heat about the pots does not exceed 70° to 75°. Place some turves, about 2 inches thick, grass side downwards, around the rims and on the surface of the pots, extending inwards about 2 inches, so as to form a dish, and outwards over the sides towards the fermenting materials with a view to encourage the surface roots to extend. Water the trees and turves with weak liquid manure, and the whole surface will soon become a mass of roots; and they may then be fed to any extent with liquid stimulants, or a sprinkling occasionally of superphosphate (bone) five parts, nitrate of potash two parts, and gypsum one part, mixed, and kept perfectly dry can be applied.

**Fig Trees Planted in Borders.**—The first house of these should now be started, and the fruit will be ripe towards the end of May or early in June, when the varieties consist of White Marseilles and Brown Turkey, the best light coloured and dark Figs for general purposes. The borders should be brought into a thoroughly moist condition by repeated waterings, but not going to the extreme of making them sodden. Syringe the trees in the morning and early afternoon when fine, otherwise only damp the floor and other available surfaces so as to maintain a genial atmosphere, for one that is close and damp has a tendency to induce soft growths and is unfavourable to the first crop fruit. Maintain a night temperature of 50°, 55° by day artificially, and allow an advance to 65° from sun heat with a free circulation of air.

**Cherry House.**—Where the house has been closed since the middle of December and frost excluded, fire heat may be applied to secure a night temperature of 40° when cold, 45° when mild, and 50° by day, allowing an advance of 5° to 10° from sun heat, but not without a free circulation of air at 50°, and admitting it abundantly in mild sunny weather. Syringe the trees occasionally, but do not keep them dripping with water, and take care that they become fairly dry before night. The roof lights having been off, the borders will not need water for some weeks to come, yet the soil must be kept in a well moistened condition. Trees in pots must be regularly attended to, not allowing the soil to become dry, but afford a supply of water when needed. If any of the trees are unsuitable, now is a good time to introduce new ones in their place. Trees that have been grown against and trained to a south wall for three or four years and lifted occasionally are the best. Early Rivers, Black Tartarian, Governor Wood, and Elton are suitable varieties. If the May Duke flavour is required Empress Eugénie will supply it, and this is a very fine variety for forcing.

**Melons.**—Plants raised from seed sown now will give ripe fruit by the end of April or early in May in light and well heated structures, not otherwise, and contingent on the weather being favourable to their growth. The seed should be sown singly in 3-inch pots half filled with fine loam and leaf soil, plunging the pots in a hotbed made of fermenting materials and covering them with a pane of glass, which must be removed as soon as the plants appear through the soil. Where there is no bottom heat the pots may be placed on shelves about 1 foot from the glass in a house with a temperature of 60° to 65° at night and 70° to 75° by day artificially, as in a fruiting Pine stove or a Cucumber house, with a piece of glass over each; and in this case the plants will be hardier and sturdier and less liable to suffer from damp than those in a hotbed. When the seedlings have made an inch or two of stem they should be top-dressed with warmed soil and kept well up to the glass or in plenty of light, so as to insure a sturdy growth. Varieties are plentiful, every grower has the best that indulges in cross-fertilisation, but good sorts adhere to types. Scarlet Gem is a standard for flavour, and Blenheim Orange with Read's Scarlet-flesh have it in larger fruit. Pine Apple (American Musk) and Egyptian have never been excelled in flavour; there is some of one or both in Davenham Early, Gilbert's Victory of Bath (an improved Bromham Hall), Hero of Lockinge, and The Countess. The Persian race have a remarkable tender flesh and a thin rind and a flavour that never cloy. Some of this "blood" has got into The Countess, and we have the old Beechwood flavour in Eastnor Castle; the Cashmere Melon characteristics being well developed in Cox's Golden Gem and in Longleaf Perfection. All are good Melons.

**Cucumbers.**—Seed must now be sown to raise plants for the early spring supply of fruit. There is none better than a carefully selected stock of Telegraph as an all-round variety; Cardiff Castle is smaller and

more prolific. We have a cross between the two, and none other will be eaten at table, but it has a long neck, and is therefore of no use for exhibition. There are many excellent varieties, the Sion House race being victorious along the whole line for cropping and using qualities, and the Long Gun breed for exhibition purposes. The seeds may be sown singly in 3-inch pots, in a rich light mould, leaving room for top-dressing the plants when they require it; plunge the pots in a brisk bottom heat near the glass, and cover with a pane of glass, which must be removed as soon as the plants appear. Where there is not the convenience of a hotbed, the pots may be stood on a shelf near the roof covered with a pane of glass, and in a genial atmosphere, with a night temperature of 65° to 70°, 5° less in cold weather, rising to 80°, 90° or more with sun; ventilate a little at 75°, but be careful to prevent a check by sudden cooling or drying of the air.

## THE BEE-KEEPER.

### APIARIAN NOTES.

THE severe weather experienced at Christmas when the thermometer registered 9°, and on the following day 7°, or 25° of frost, was followed by the densest fog ever experienced in this locality. At the time of writing, however, it is milder but still frosty. Although the frost was unaccompanied by snow, flowers and vegetables are so far very little affected.

Bees have had nearly two months of almost arctic winter, but the atmosphere has been drier than we have usually experienced at this season, consequently the bees have wintered well, and as they are more likely to suffer in December than further on, we consider them safe, provided they lack nothing, and are free from moisture.

Breeding has commenced in many hives having youthful queens. The cluster will expand, and a greater heat kept up, which enables the bees to resist a very low temperature, should it come on unexpectedly.

Entrances will not be interfered with until the bees make an effort to enlarge them; and even after that we may again contract them to their normal winter's width, which in no case exceeds 1 inch, some of them half of that. Our hives have an immunity from dead bees on the floor, the result of small entrances and the absence of damp. We do not require to clean floors, nor use a "hooked wire" to clear out the bees that "died from old age," nor do we see a single speck of evacuated matter on any one of our hives.

I am interested in a weak hive, which will elucidate a matter of no little importance on the wintering problem and general management. It has a queen of the normal length, but less in girth by a third than the average queen. Started with less than a hundred bees on the 1st of August, and supplemented with about 300 cells of ripe brood, the bees were fed sparingly till the middle of November with 9 lbs. of sugar. The hive is in a healthy state, and I have observed one dead bee only from it. The bees occupy two divisions of a Lanarkshire hive, and which has a very small entrance. Had these bees an entrance of 3 or 4 inches probably they would have been all dead from "old age," so we prefer keeping them young and alive.

When floors are unventilated cleansing them should not be delayed. Fixed floors should not be tolerated by those having the welfare of the bees at heart. January has never failed to give us several days for such operations or to feed hives short of stores.

Where quilts are used they should be examined, and if damp removed, fresh dry ones being substituted. Where dried grass is used the task is unnecessary.

Dysentery results from damp or a draught, and both of these hinder breeding, and are direct causes of unprofitable hives. The queens of such hives are liable to disease, and although young bees are not brought forward eggs are proportionately deposited as if they were.

### TWO QUEENS IN ONE HIVE.

The following is an extract from a letter I received about the time the subject was sprung upon the public as "new." "I was much surprised on reading the B.K.R. that 'W. B. C.' claims the idea a new one. I sent you some time since specimens of the frames I had from you nearly thirty years ago, calling your attention to similar frames being patented in England by ——. The hives these frames were from were also intended for two queens, and your instructions accompanying them say distinctly the side extension is for working two queens in one hive if desired. It astonishes us hereabouts that an Editor could so commit himself and mislead those of his readers who did not know better."

### SEVERE WINTERS.

These have not the terror with us for the safety of our bees they had long ago, and hives made specially for that purpose were

too cumbersome for moving about. It is a much better plan to winter stocks singly and unite brood, bees, or both at the proper time. Further hints will be given in subsequent articles, meanwhile wishing a profitable and Happy New Year to all.—A. L. B. K.

#### THE TITS AND THEIR HABITS.

I CANNOT say that I have observed any of the tits injuring fruit buds here. I am sorry to say, however, that I must agree with those who state that they find *Parus major* eat their bees. I have seen the large tit station itself at the entrance of the hive and pick up the bees as they emerged. This is in spring, and I have stood watching and rather admiring the little bird's dexterity. I have no doubt our worthy friend "A. L. B. K." will hardly approve of my indifference to the destruction of the bees. I fear, however, that I prefer flowers to bees, and would have been in a different frame of mind had it been the former which were attacked by the tits. I asked a local bee-keeper, who is in addition a great observer of birds, if he had seen the tits eating bees. He said, "Yes, every spring." It was always the large tit he had also seen.—S. ARNOTT.

#### TRADE CATALOGUES RECEIVED.

Biddle & Co., Loughborough. — *Flower and Vegetable Seeds, Bulbs, &c.*  
G. Bunyard & Co., Maidstone, Kent. — *Vegetable and Flower Seeds.*  
W. Cutbush & Sons, Highgate, London. — *Flower, Vegetable, and Farm Seeds, and New Chrysanthemums.*  
E. P. Dixon & Sons, The Yorkshire Seed Establishment, Hull. — *Vegetable and Flower Seeds and Choice Chrysanthemums.*  
Dobie & Dicks, 66, Deansgate, Manchester — *Price List of Seeds.*  
H. J. Jones, Rectcroft Nurseries, Hither Green, Lewisham. — *Chrysanthemums.*  
W. Paul & Son, Waltham Cross, Herts. — *Seeds and Garden Sundries.*  
R. Veitch & Son, High Street, Exeter. — *Kitchen Garden and Vegetable Seeds.*

\* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**National Chrysanthemum Society's Catalogue (H. R.).**—We think the best way in which we can help you will be by forwarding your letter to Mr. Richard Dean. There appears to have been an oversight, accidental we are sure, or perhaps the Secretary is waiting the publication of the new issue before writing you on the subject.

**Chrysanthemum Cuttings (W. G. S.).**—If you wish to retard the growth of cuttings you had better plant out the stools after the frost departs in a cool position in the garden. Cuttings of low growing varieties inserted in May, June, or July make useful dwarf decorative plants. If severe frost occur after planting, spread some litter over the ground. The stools should be prepared in a cool frame.

**Gloire de Dijon Rose in Greenhouse—Tuberose—Cutting Down Duchess of Edinburgh Clematis (Hittite).**—1, The Rose could only be expected to develop its buds or make growth in a temperature of 45° to 55°, but there will be no harm in that if the house is not kept very close. A temperature of 40° to 45° at night and 50° by day, with a free circulation of air above that point, would have been more suitable; but it would not now answer to lower the temperature, as that would check the growth and probably cause the buds to drop, therefore keep as at present—it will give you flowers earlier. 2, The Tuberose should be gradually withdrawn from their position on the hot-water pipes after they have started into growth and before they become drawn, placing them on the greenhouse shelf, but not where draughty, or they will be stunted and fall a prey to red spider. They were started too soon. 3, Duchess of Edinburgh Clematis is of the Florida type—blooming from the previous year's ripened wood from June to July (outdoors), and is useful for conservatory decoration. The pruning of the plant in your greenhouse now may be done; it consists in the removal of all weak wood; a portion of the old flowering

wood should also be shortened to near the base, so that young growths for the following season's bloom may be secured, but a sufficiency of flowering wood for the current year's blooming must be retained—the best and strongest. The variety has pure white flowers, sweetly scented.

**Plants in Vinery (Somerset).**—We should not lower the pit, unless for tall plants, as the nearer plants are to the light the better. Stout boards would make a very good stage for such a place, be useful for standing upon in thinning the Grapes and otherwise attending to the Vines. Camellias do fairly well in vineries, standing them outdoors after the buds are set and housing them at the end of September. *Alba plena*, C. M. Hovey, *Lavina Maggi*, and *Mrs. Cope* are good varieties. *Azaleas* would flower in the spring; *Deutsche Perle*, *Jean Vervaene*, *Kaiser Wilhelm*, and *Vesuvius* are fine varieties. Of smaller plants you may have *Epacris hyacinthiflora*, *The Bride*, *Vesuvius*, and *Lady Panmure*; *Libonia floribunda*, *Coronilla glauca*, *Primula sinensis*, *Sparmannia africana*, *Vallota purpurea*, and other plants; but they will need considerable moving about so as to meet their requirements, as no flowering plants will succeed beneath Vines in full foliage. Ferns, ornamental-leaved *Begonias*, and *Palms* are suitable for vineries in summer.

**Aleyrodes (T. C.).**—The following note from Mr. Iggulden exactly answers your question:—The white fly on Tomatoes is almost as much to be dreaded as fungoid diseases, a bad attack completely paralysing the growth of the infested plants. Unfortunately the remedies for getting rid of this pest have a most prejudicial effect upon the flowers, and ought therefore to be applied and persevered with before the plants are far advanced in growth. As far as many market growers are concerned, a thorough clearance of Tomato plants from the place, all being burnt, and the houses filled with strong fumes of sulphur, will usually get rid of the *Aleyrodes*, what few that do escape being easily kept down by means of a sulphur dressing on the hot-water pipes. Syringing the plants with a rather strong solution of carbolic soap has been found a fairly good remedy, but must be persevered with to be quite effective. So also are frequent fumigations with tobacco paper. One or two fumigations are not enough, this not greatly injuring the eggs and partially developed insects to be found on the under side of the leaves. All things considered nothing answers so well as sulphur fumes generated with the aid of hot-water pipes. Mix flowers of sulphur with either milk or linseed oil, and paint the flow-pipes with this. Whenever it is necessary to fire rather hard in order to keep out frosts or to prevent the temperatures falling rather low, the fumes will be given off strongly, and also during a spell of bright sunshine coincident with a brisk heat in the pipes. Two or three sulphur dressings should be given during the winter, and the chances are not a fly will survive till the spring. Better run some risks of the loss of a few flowers than the greater one of the plants being smothered by the "honeydew" of the white fly and the certain depreciation in the weight of crops produced.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (T. K.).—*Lælia autumnalis atro-rubens*. (Somerset).—The specimen sent has no relation to the Cinnamon, which belongs to the Laurel family, while your plant appears to be one of the Gingerworts and is probably an *Hedychium*.

#### COVENT GARDEN MARKET.—JANUARY 4TH.

Trade still very quiet, with supplies quite equal to the demand.

##### FRUIT.

## THE NEW YEAR.

THOUGH the gloom and sadness of hard times hung like a heavy fog over the last hours of the old year, we do not enter the new year without hope of bright days to come, of a renewal of prosperity even in agriculture. That this is possible we have not a doubt; the difficulty appears to be in seeing how it is to be managed, and our first article this year may well be devoted to the good work of clearing the way for a change that is inevitable.

For our hope of bright days to be realised we must not expect to have what is so clearly impossible—i.e., Wheat at anything like £3 or £4 a quarter. That is a thing of the past; with such prices it answered to sow everywhere, but now it is only in good, deep, rich, mixed soil that Wheat can be grown at a profit. The matter is very simple; the average Wheat yield in this country of 29 or 30 bushels an acre means a loss, the possible Wheat yield of 40 to 48 bushels an acre means a profit. Let this be clearly understood. Further, let the man who persists in sowing Wheat in poor or badly tilled soil understand that he alone must suffer for his folly, and that he has no just claim upon his landlord or his country for assistance. We may be—nay, we have been—told that a certain quantity of Wheat straw must be grown for rick thatching, and for the stable and hovel litter. Our answer is, Sow Oats; be satisfied with nothing less than 80 bushels an acre, and you will have plenty of straw both for food and litter, and corn for all live stock on the farm. Nothing fattens poultry or pigs better than oatmeal; nothing keeps ewes heavy with lamb in condition better than crushed Oats; for horses, cows, bullocks the food is alike excellent; and remember that, though thin Russian Oats can be bought so cheaply, a really heavy British Oat is far more profitable. Resolve for one thing in the new year to give this matter a fair trial. Procure really fine seed, weighing quite 40 lbs. per bushel, sow early and thickly, and drill with the seed per acre 1 cwt. of nitrate of soda, the same quantity of superphosphate, and half a hundredweight each of steamed bone flour and muriate of potash. If you have any doubt about the matter try it on a small scale—say, in a single field, and prove for yourself how profitable it is.

Apply this common sense principle of thorough culture to all farm crops. As Professor Wrightson said recently, "Rent, rates, til'ages and seed, are equally expended upon all crops, whether good or bad." Just so is it with farm stock—the bad cost even more to feed than the good—a poor Irish steer is a far more costly animal to rear than a choice home-bred beast,

but even the home-bred animal must have ample shelter and food now. We are told that thousands of beasts were grazed at a loss in the Midlands last year: we do not wonder. Go through the dairy farms of Leicestershire and Derbyshire now, and see, if you can, how the half-starved store cattle out on the pasture, without shelter, and with so little food, can be expected to answer? Here a change to fewer numbers, more substantial food, efficient shelter, would certainly be a change for the better—grazing for profit instead of for loss—and the graziers who keep their cattle in such wretched plight all winter have no more claim for pity than incompetent Wheat growers. Both have the right and wrong way set before them; let them help themselves before crying out for help from without; then, when they have shown themselves worthy of assistance, it may, if found necessary, be accorded them.

With advanced rates by railway companies for milk carriage, an outcry is a certainty. But the railway carriers consider their action justifiable, because the milk carriage is a bulky unprofitable business in comparison with that of the minerals which form so large a bulk of the business of the great companies north of London. If only the effect of the higher rates is to check the sending of milk to London from such long distances, and to induce the establishment of farmers' co-operative cheese and butter factories, it will do much good. We have repeatedly shown how, if the milk supply of the metropolis and other large towns were confined to a given radius, it would tend to raise the price of milk both for the producer for towns, and for the factories outside town supply boundaries; there would also be a great saving upon the present heavy outlay for carriage by rail. Such a highly desirable change can only be effected by co-operation. We believe it will come by such means in due course, as also will the better production and disposal of all farm produce. Self-help as a body, as well as individually, is what farmers require very much more of to meet hard times. The burdens on the land may then be lightened too, both in rating and taxation; butcher and baker will then be met and fought on their own ground; and the co-operative factory dairy shops, with a steady supply of first-class butter, will soon drive the inferior Danish and Brittany butter out of the market. Imported butter now on sale may have the merit of uniform quality, but that is all that can be said for it, and it is always devoid of the delicious flavour of really good butter.

## WORK ON THE HOME FARM.

Advantage has been taken of the hard frost to cart firewood of all kinds for home use, also gravel for roads and paths, chalk for the bottoms of yards, and lime for the land. All such work is pushed on with now in order to avoid any hindrance from it in spring when horses and men are required upon the land. Our handy man is overhauling farm implements for cleaning, repairs, and painting, which should be done at least once a year. Under good management each tool or labour-saving appliance is kept in such perfect order that it is ready for use when wanted. How frequently have we seen mowing machines sent off for repair just when mowing is beginning with the vexatious certainty of having to wait for them and losing several fine days! Instead of being placed away dirty and broken in any shed or outbuilding till wanted we would have all implements kept together trim, neat, bright, and efficient as care and pains can make them. We earnestly invite the attention of home farmers to this, which if it is a mere matter of detail is one of sufficient importance to merit their best attention.

Let the lambing yard or fold be got ready for use. Oats and Peas in stack near the fold should be threshed and the straw restacked close at hand for use. Have plenty of straw cut into chaff, Oats crushed, and ample supplies of all food at hand for the shepherd. Two or four-toothed ewes may not require crushed Oats, but they are decidedly best for full-mouth ewes and all animals of mature age. Keep plenty of Pea straw in racks for the sheep, and see that they have chaff and Oats in the troughs twice daily. Use few, if any, roots during the prevalence of very cold weather. This is a matter about which shepherds are not to be trusted, from the common idea that roots are good for the milk, and they will have the roots if they can get at them. After the lambing we allow a regular supply of roots with other food, but roots are not to be regarded as indispensable. With plenty of silage roots can be dispensed with. The silage is much the cheaper article of diet, ewes and lambs like and thrive upon it, and it ought to enter largely into every scheme of farm management. Provide cribs for the separate use of each

ewe immediately after the lambing, make a point of each ewe being kept there till it allows the lamb to suck freely, and it is seen to take food well and to be in satisfactory condition. Then it may go to the large general fold where other ewes and lambs are kept at night and on rough days till the lambs are well advanced in growth and strength.

### REPORT OF THE CLOVER AND GRASS SEED HARVEST OF 1892.

THE seed harvest for 1892 was a memorable one in many points. It will be remembered that in 1891 we had to report an unfavourable condition of things, which was fully substantiated long before the English sowing season had approached its end. The scarcity of fine quality Clovers in particular became early apparent and caused values to rule very high. At a later period the entire absence of these higher grades left an opening for the cheaper classes which were readily snapped up, and as a consequence the new season opens with a market that is absolutely bare of yearling offerings.

In England the circumstances governing the new crop are very similar to those prevailing at the previous harvest, a long and severe winter followed by a generally ungenial summer with an over-abundance of autumn rains, has brought about a very unsatisfactory result, and in addition to this unkindness of the season at home, in Germany the crop is short, and, owing to the drought, for similar reasons the crop in France is almost a failure. In America the outlook is uncertain and unfavourable, prices rule high, and samples are weak, washy, and inferior.

**RED CLOVER** (*Trifolium pratense*).—The English crop, which a month or two ago promised to be an average one, has been seriously interfered with by the late rains, and is likely to come considerably short of earlier estimates. The quality, it is anticipated, will under any circumstances be better than last year. Continental reports, including Italy, Germany, Denmark, Holland, and Russia, are very conflicting; in some districts a fair yield of sound seed is expected, whilst from others the accounts speak of short and unsatisfactory crops. The crop in France is so far a failure that they have none to export, and are buyers rather than sellers. The American crop is reported from 10 to 20 per cent. under the average, and this yield, if taken as correct, means that little will be exported. Judging of the standard qualities from samples that have come into our possession, it may be reasonably expected that the Red Clover crop, taken all round, will be a short crop in all the chief producing districts.

**WHITE CLOVER** (*Trifolium repens*).—In England a larger acreage than usual under this Clover bids fair to show extra good quality. From the Continent all sorts of statements reach us. From Moravia and Silesia we are told the harvest is bad; from Poland and Bohemia we learn that the output is exceedingly meagre; from certain parts of Germany and France we hear of better things from some localities. American reports present a material shortage in quantity, with small seed, wanting in quality. So far as we have handled samples, the European seed, although bright, is small in grain and very dirty.

**ALSIKE CLOVER** (*Trifolium hybridum*).—The small English acreage held promise of a fair yield a month or two back, and it remains to be seen how far the last incessant rains have interfered with this prospect. Reports from Germany, Austria, and Sweden are so far satisfactory. From Canada the latest information speak of a good crop, well harvested; the quantity of actually available seed, however, is unfortunately restricted by a deficiency in the area under cultivation.

**COW GRASS** (*Trifolium pratense perenne*).—In direct sympathy with Red Clover, this crop is likely to be much under the general average, and really choice parcels will as usual command good money.

**TRIFOIL** (*Medicago lupulina*).—is reported below the average. Samples we have already handled are bold but somewhat discoloured; choice and bright seed is held at exceptionally high rates. This crop, however, is always an extensive one, both at home and abroad; and whilst the fine grades are certain to go dear, medium qualities will in our opinion be obtainable at more reasonable figures.

**LUCERNE** (*Medicago sativa*).—An under average crop is reported, and prices may be expected to have an upward tendency.

**TIMOTHY** (*Phleum pratense*).—Unfavourable accounts are given of this crop, both in America and Germany, and higher figures are expected to rule. The British crop is too infinitesimal to affect values.

**RAPE** appears to be a fair average crop, harvested, both at home and abroad, in excellent condition. The samples now offering are very black and dry.

**WHITE MUSTARD**.—This is a disappointing crop, poor in quality and bad in colour. The quantity under cultivation seems much smaller than usual, and what is consequently a scanty harvest has been largely bought up by the mustard grinders. The values now prevailing for this article are higher than they have been for many years.

**CANARY** still stands at a very high figure, in consequence of unsatisfactory reports from the leading producing districts.

**SWEDES AND TURNIPS**.—The advent of the new crop has caused prices of many varieties to ease a little. The harvest, however, is a short one in most districts, and values, more particularly of Swedes and Scotch Yellows, are likely to continue high.

**PERENNIAL RYE GRASS**.—Little of one-year-old seed appears to have been left over, either of Scotch or Irish growth, consequently prices have ruled high throughout the summer. The new crop is reported from all parts to be deficient in yield, but this seems to be partly met by an increased acreage under growth. There is no doubt the long and con-

tinued winter seriously prejudiced the prospects of the plant, particularly in the seaboard districts in the south of Scotland, and as a result the natural weight per bushel is certain to be some pounds lighter than in an average season. Prices are likely to advance.

**ITALIAN RYE GRASS**.—In close association with its more permanent relation, this useful Grass is reported short from all parts, both in Great Britain and France, for the same climatic reasons. At the present time values are about 50 per cent. higher than those prevailing in an ordinary year; and these figures will be most likely maintained.

**MANGEL**.—This crop has been sadly affected by the hard winter, which killed a large portion of the bulbs out for seed, and is likely to come in very short in quantity and deficient in size. The continental crops are in many parts in direct sympathy with our own, and it is only in favoured districts, that have escaped the weather, that anything like a satisfactory yield is expected.

### NATURAL GRASSES.

**ANTHOXANTHUM ODORATUM** (Sweet Vernal).—There is a very poor crop of this Grass, the plant having suffered severely from frost during the period of tender growth.

**AGROSTIS STOLONIFERA** (Fiorin).—This is reported as under the average crop both in Germany and America, and prices are likely to rule high.

**ALOPECURUS PRATENSIS** (Meadow Foxtail).—This is again one of the shortest crops in Germany. On the other hand, the Russian and Scandinavian harvests are reported an average. Clean seed, free from maggot, is likely to command good money.

**CYNOSURUS CRISTATUS** (Crested Dogtail).—This Grass is the mystery of the season, being practically a failure in England, Ireland, Holland, and Germany, and all other producing districts. In our own experience a grower who controls a large producing district, and who we usually look to for ten to twenty tons at least, is only able to offer two to three tons, and that at an almost prohibitive price. In view of this the values must remain abnormally high.

**DACTYLIS GLOMERATA** (Cocksfoot).—There is every likelihood of a sufficiency of this Grass, what with the New Zealand, American, continental, and British crops, to meet all ordinary demands.

**FESTUCA TENUIFOLIA** (Fine-leaved Fescue).—This crop is usually very light. Reports state that even less has been harvested this season than the preceding year, which gave a very limited supply. As its principal use is in the formation of lawns and pleasure grounds, this Grass is not an important factor in the supply.

**FESTUCA DURIUSCULA** (Hard Fescue).—Is again under an average crop, and prices are likely to advance considerably.

**SHEEP'S FESCUE** (*Festuca ovina*).—The same may be said of this useful Grass.

**FESTUCA PRATENSIS** (Meadow Fescue).—Both in Britain, Germany, and America this Grass is reported exceedingly short, and more money is already asked for fairly clean samples. The small quantity at present produced in New Zealand scarcely affects the market.

**FESTUCA ELATIOR** (Tall Fescue).—This Grass is even less plentiful than in previous years, and true samples will command high prices.

**POA TRIVIALIS AND NEMORALIS** (Rough-stalk Meadow Grass and Wood Meadow Grass) are average crops of generally inferior quality. Heavy and well matured samples will secure high prices.

**POA PRATENSIS** (Smooth-stalk Meadow Grass).—Reports from the Continent and America speak of a good average crop, and prices will be much more reasonable than of late.

As in previous years, there is an abundance of inferior Grass seeds of all kinds in the market at all sorts of prices.—JAMES CARTER AND CO., High Holborn.

### REMARKS.

25th.—Almost cloudless throughout.  
26th.—Cloudless morning; bright afternoon and evening.  
27th.—Rather dense fog in morning; clear after 1.30 P.M.  
28th.—Fog all day; dense in morning and evening.  
29th.—Fog, generally very dense, till 11.30 A.M., when it cleared completely and very suddenly, but began to accumulate again soon after noon, and was thick by 1 P.M.; cleared again at night.  
30th.—Fair, but slightly foggy in morning.  
31st.—Overcast, but free from fog.  
An absolutely rain and snowless week, completing a drought of seventeen days. Very foggy and extremely cold. Only one week has been equally so (December 20th to 26th, 1891) for at least ten years.—G. J. SYMONS.

SO long have we been accustomed to the Snowdrop withholding its pure blossoms from our view until the last days of January or early February, that the public mind has been slow to recognise that there are not only Snowdrops which bloom in midwinter also, but others which come in October to give our gardens a new charm in the time when flowers are becoming few and far between.

So long, too, has the Snowdrop of our gardens and parks remained the child of nature, untutored and unchanged by art, that we are almost unwilling to believe that this "early herald of the infant year," with its chaste and simple blossoms, may be constrained to produce varieties which will yield us flowers of larger size, of varied form, and of other markings. To me, for one, for long these changes were unwelcome, and it was with feelings in which some dread of seeing the Snowdrop attain the status of a "florist's flower" was predominant that some years ago I began to see that a new destiny awaited this simple flower. Further reflection, however, shows on what shallow basis this dread was founded. The Daffodil, for instance, has lost nothing, but has vastly gained by the labours of Leeds, Backhouse, and the more recent cultivators who have sought to add new forms to our gardens. Nor has Dame Nature herself, even in the Snowdrop, taught us a lesson of immutability, for many examples of her work in yielding us new varieties are coming into view, and where she has led the way we need not disdain to follow.

The Snowdrop Conference of the Royal Horticultural Society, held on March 10th, 1891, may be said to have marked a great step in the movement for the increased cultivation of the species and varieties of the *Galanthus*, which has been slowly making its way among a limited number; and it is to be hoped that this movement will make still greater headway, checked though it is by the difficulty, or rather impossibility, of obtaining many of the newer introductions through the medium of the ordinary trade sources. It is with the view of adding some slight impetus to this movement that these notes are penned, incomplete as they necessarily are, the literature of the Snowdrop being now too extensive to permit of its condensation into the limits of this article.

Treating of the Snowdrops in cultivation in the order of their flowering we have, as the pioneer of the genus, the early *Galanthus octobrensis*, blooming in Britain in October or early in November. This is a pretty but delicate flower, partaking of the character of *G. nivalis*, of which it is in reality only a variety or a sub-species. This Snowdrop was first introduced into this country by the late Rev. Harpur Crewe, who received bulbs from Lord Walsingham, who had collected them on one of the Albanian mountains.

Following *G. octobrensis* are some other varieties, which are as yet too rare, and have been too short a time in our gardens to speak with any certainty of their average blooming time. Of these *G. Rachelæ* and *G. Elsæ* are in cultivation, but are so rare as to be almost priceless. The former was collected by Professor Mahaffy on Mount Hymettus in 1884 or 1886. This was in leaf in Dublin in December, and I have a bulb, received under this name, which is also in leaf, but it is quite possible that mine may not prove the true sort, as there are several winter-flowering varieties at present going under the names of *G. Olgæ*, *G. Rachelæ*, and *G. Elsæ* on the continent. Of the authenticated *G. Rachelæ* there are very few bulbs in existence, and I should be glad to possess one of these.

*G. Elsæ* was in bud in Dublin in December, but it has been known to open earlier. *G. Olgæ* is at present in uncertainty. It was originally found on Mount Laygetus by Orphanides, but unfortunately, on account of his sad illness, no further trace of it seems to have been found. *G. Elsæ* was brought from Mount Athos by Professor Mahaffy.

In all probability, however, it will be found that *G. coreyrensis* or *præcox*, said to have been sent from Corfu to the Rev. Harpur Crewe, is the Snowdrop which in ordinary seasons will succeed *G. octobrensis*. This flowered with me in the end of November, 1892, but it generally flowers from the middle to the end of December. This is a small but pretty form of *G. nivalis*, to which species *G. Rachelæ* and *G. Elsæ* also belong. It, like all the other autumn-flowering varieties, possesses the glaucous line down the centre of the leaf, which is a noteworthy feature of these varieties. There are several Snowdrops from Corfu, of which little can be said, for the sufficient reason that they have not yet been properly named, and in all likelihood some of these will be offered under the names of some of the rare varieties being inquired for. I have two bulbs from the continent, as "received from Albania, and probably *octobrensis*." They are only in bud, and although of the autumn and winter-flowering type it is likely enough from their appearance that they will prove to be bulbs of *G. coreyrensis*.

The next to bloom in our gardens is *G. Elwesi*, one of the finest of our Snowdrops, although having the defect of failing in some gardens, and also of being weak in the stem. Mr. Allen of Shepton Mallet, to whom, in a very great degree, the movement in favour of the Snowdrops is due, is endeavouring to raise seedlings of a more vigorous type, and it is to be hoped that he may be successful. *G. Elwesi* is very distinct, not only from the inner petals being arranged in a tube-like manner, but also from the dark green basal blotch extending to half their length. There is a very considerable variation in this species, and several superior forms are at present in process of selection. Mr. Allen has found some with the inner petals almost entirely green, and Mr. Boyd of Melrose has raised a seedling which flowered for the first time in 1892, and which is entirely white. According to Mr. Baker's "Handbook of the Amaryllideæ," *G. Elwesi* was discovered by Balansa in 1854, but was only individualised in 1875 by Mr. Elwes. Mr. Baker gives February as the flowering period in this country, but I have found this species flowers very early in January in ordinary seasons with me. This season it is later than usual. Imported bulbs are, however, earlier, and have been showing flower from early in December. I have also under observation bulbs received from the Bithynian Olympus, and marked by my correspondent as probably *G. Elwesi*. The leaves, however, appear broader than those of *Elwesi* which has been introduced from the mountains near Smyrna. I can find no note regarding the *Galanthi* of the Bithynian Olympus, and am in hope that I may find something near *G. Fosteri* among my bulbs. *G. nivalis*, our common Snowdrop, has proved much more variable than is generally believed.

Besides the various autumn varieties already noted, those which flower in spring vary considerably. Taking these varieties in alphabetical order we have *G. æstivalis*, a very pretty and distinct little Snowdrop with bright green markings, and flowering much later than the type. I have had this for some four or five years, and find it very useful for cutting purposes. *G. Cathcartiæ* found, I believe, in a Scottish garden is a form with twin spathes and no green markings on the sepals. *G. flavescens* has yellow markings on the inner petals and a yellow ovary. This was found in Northumberland by Mr. Boyd, and it is found a stronger grower than *G. lutescens*, which is of somewhat similar character, but with the yellow of a paler tint. This was also found in Northumberland, but in a different garden, and by Mr. Sanders of Cambridge. *G. major* is said to be a large flowered form of *nivalis*, and is one which I only succeeded in obtaining last autumn.

*G. n. Melvillei*, a seedling raised at Dunrobin Castle by Mr. D. Melville, is a fine variety with stouter and longer leaves and stem and large flowers. *G. n. pallidus* is a pale green marked variety of rather earlier habit than the type. *G. n. poculiformis* was originally raised at Dunrobin, but afterwards found also in Wales. This has the inner perianth segments nearly as long as the outer, and the green markings are entirely absent. *G. n. reflexus* does not seem to be in cultivation, but I understand the name is given on account of the inner segments being partly reflexed. A double form of this has been catalogued, but I have found it not forthcoming when ordered. *G. Scharloki* has twin leafy spathes and large green spots near the base of the outer sepals. *G. n. serotinus*, another Dunrobin seedling, is a very small form, flowering even later than *G. æstivalis*. *G. virescens* is more valued as a curiosity than for its beauty, the sepals being striped with green near the base and the inner petals nearly all green except the margins. The ordinary double form of *G. nivalis* is well known, and in addition there are a few seedling doubles which have not yet been distributed.

There are a considerable number of other forms of *G. nivalis*, varying in form, stature, and markings, and it is highly probable that others will be found in gardens now that attention has been more widely attracted to the existing varieties. I have heard of plants of *G. nivalis* which were found near Galston in Scotland, and which had stems 20 inches in length and with flowers of proportionate size. The bulbs were lifted, and are being grown in order to ascertain if this large form will prove permanent, or is only due to exceptional soil or position.

*G. Imperati*, which is a sub-species of *nivalis*, has broader leaves and larger flowers. It is a native of Naples and Genoa, and, like the other sub-species, *G. caucasicus*, has produced some fine varieties. *G. I. Atkinsi* is one of the finest of these, being of large size and great purity of colour. I am indebted to Mr. Allen for this variety, and for some others. *G. Imperati Boydi* is another very fine form, having flowers occasionally  $1\frac{1}{2}$  inch long. *G. caucasicus*, which is the Caucasian form of *G. nivalis*, has broader leaves than the type, and is later in flowering. According to Mr. Baker this sub-species includes *Redoutei*, *major*, and *caspicus* of Ruprecht. Mr. Baker also seems to consider *G. virescens* a variety of *G. caucasicus*, although Mr. F. W. Burbidge only mentions it as a variety of *G. nivalis*.

*G. latifolius*, which flowers in this country in February and March, is a very distinct species from the Caucasus, with broad shining green—not glaucous—leaves and small white flowers  $\frac{1}{2}$  to  $\frac{3}{4}$  inches long, with only a green patch in the outside and inside of the inner segments. There is a fine variety of this called *latifolius major*.

*G. Fosteri*, introduced from Amasia in the province of Sirwas, Asia Minor, and named in honour of the introducer, Professor M. Foster, is one of our latest acquisitions, which has been the subject of considerable criticism, due to its presenting much variation. It is supposed to be a hybrid between *G. latifolius* and *G. Elwesi*, and has broad green leaves with somewhat similar markings on the flowers to those of *G. Elwesi*. The first of this which I bloomed gave me considerable disappointment, but other flowers caused me to modify my earlier opinions, and the best forms are well worthy of cultivation.

*G. plicatus*, readily recognised by its plicate leaves, is now fairly well known. It is a native of the Crimea, and, although not so well formed as some of the others, is valuable from its late flowering habit, it being the last in flower. Several varieties are now in cultivation, some of these being seedlings and others selected forms. Two found by Mr. Boyd of Melrose in a garden in Berwickshire are good forms which should be obtained if possible. The first, *G. p. maximus*, has long narrow flowers which in favourable conditions are quite 2 inches long. The other, *G. p. Chapeli*, has smaller flowers, but these are of fine form and with broad petals. In the *Journal* in 1892 I noticed several hybrids raised between *G. plicatus* and *G. nivalis*, by Mr. W. Thomson, of High

Blantyre were described. Mr. Allan has another seedling, apparently of the same origin, but not obtained by artificial fertilisation.

These notes, although long, are much condensed, and much of great interest remains unnoticed. I hope, however, as some of the Snowdrops come into flower to have the opportunity of supplementing this article. May I, however, ask those who grow Snowdrops extensively to pay careful attention when they come into flower? We do not want merely trivial distinctions, but varieties of distinct merit. May I also urge those who are raising seedlings to adopt names more in keeping with the character of the flower than are sometimes applied to flowers? I do not think such titles as *Goliath*, *Champion*, or *Longshanks* would be considered appropriate.—S. ARNOTT.

## ECONOMICAL GARDENING.

AT the beginning of another year the thoughts of all gardeners will be largely occupied with plans and prospects concerning the future. Some will happily be able to pursue the even tenor of their ways with plenty of help and ample pecuniary assistance at their command wherewith to maintain in high keeping the gardens under their charge. The majority, however, are forcibly reminded that rigid economy must still be the order of the day. They know, too, to how great an extent this increases their difficulties, as they have economic as well as cultural problems to solve. This being so, it is no use to ignore the fact that a due regard to economy has become a necessary part of a gardener's training. Many men who have proved themselves to be splendid cultivators while every convenience was at their command cut but a sorry figure when they have to "garden under difficulties," and others have the knack of producing splendid results under circumstances which would bewilder less tenacious individuals.

One of the best and surest methods of promoting economy is to provide suitable work for the weather and occasion. When no time is wasted and each man takes a real interest in his work it is surprising how much can be accomplished. No one can make satisfactory progress with work of any kind while his limbs, if not his whole body, is benumbed with cold. In some callings which offer but little variety of work it is not easy to apportion the task according to the weather; it is, however, not so with gardening. Not a few individuals are possessed with the idea that the autumn and winter months are slack times in gardens. Such erroneous impressions may be easily dispelled by a year's sojourn in any well managed garden, for in such establishments there are no "slack" times.

If things are to be kept up to the best state possible according to the labour at command, a great number of important details must receive attention during the winter in order to lighten as far as possible the work of summer. The disastrous season of 1892 has affected landlords all over the country in a marked degree, so much so that economy in the garden will have to be put to severer tests than usual in many gardens. Already I have heard of reductions taking place in several establishments, and in others a considerable shortening of hands during the winter months. The latter proceeding I think few who have thought much about the matter will admit to be a work of real economy. To my mind, a far better policy, in cases where the expenditure has to be kept within a certain limit, is to keep a given number of regular hands, and to do the best that can be done with them, except at especially busy times, when a little extra labour is well employed, and work is given to men who make a speciality of short terms of service. In this way all who are employed retain a thorough interest in the work, and with good management in other respects places which are in reality conducted under adverse circumstances are apparently well kept.

Much of the work which in some places is left to the busy spring months may with advantage be performed in winter. I am a great advocate for giving garden walks more attention during the winter than they usually get, as I am confident that a vast amount of spring labour is by so doing rendered unnecessary; and, moreover, walks so treated are kept in better condition throughout. The keen frosty weather lately experienced has been especially suitable for this kind of work, and our own have received a thorough clearing, which will do much towards keeping them clean and bright for some time to come. Our plan of procedure is to go over them with the Dutch hoe, and scrape off the few weeds which are found. This is easily done now, as the gravel is as hard as a rock and the weeds brittle, which combination of circumstances enables the operator to remove them quite down to the roots without disturbing the gravel; any parts which have become green or discoloured are also scraped. The whole surface is then

brushed hard with a stiff broom, and the *débris*, which is chiefly sand and dust, wheeled away. When this is finished a smooth, bright surface is the result. Walks so treated do not become soft and spongy when the frost breaks to so great an extent as do others not so treated, simply because the fine particles removed would, if left, have formed a thin but still sufficiently thick coating of adhesive matter to cause the gravel to "take up" when walked upon.

The carting and wheeling of manure wherever required is another matter which has been carried out expeditiously during the late clear frosty weather. The large mass of rubbish of various kinds which accumulates during the summer months should also be dealt with, the rougher portions being burned, and the decaying parts thoroughly separated and thrown into a heap ready for carting away, so that the space set apart for the rubbish heap may be cleared up ready for another year's constant stream of refuse. These are all matters which should be pushed on with during fine frosty weather.

When wet or snowy days prevail all the labour available can be

CATTLEYA LABIATA ALBA.

WHEN the vast importations of *C. labiata* made by Messrs. Sander & Co. were disposed of, it was expected that in due course some noteworthy variations from the type would appear somewhere or other amongst them. The most remarkable example that has yet appeared is the pure white form represented by fig. 4, and which has flowered in the collection of M. Wells, Esq., Broomfield, Sale. It requires no detailed description, for it is a counterpart of the type in form; but the sepals, petals, lip, and tube are

FIG. 4.—CATTLEYA LABIATA ALBA.

pressed into work under cover, of which there is always plenty, let the winter be ever so long. Large stocks of brooms, sticks, labels, and pegs should be got in readiness, so that not a moment of fine summer weather is spent on such work. Tools also need mending, sharpening, and re-arranging; boxes for the propagation of bedding plants should also be made; pots ought to be washed and stacked away in sizes ready for use; and any other labour which can be spared be utilised to complete the annual clearing of houses, plants, and the top-dressing of inside fruit tree borders.

When dealing with plants infested with insects of any kind it is true economy to use freely some of the many excellent insecticides. With the use of these one man will in a few hours destroy as many insects as three could do with the use of sponge and stick or brush. Hours innumerable have been wasted at this kind of work.

Those who pay due attention to all these matters during the short days of winter will find their time quite as precious then as in the height of summer, and, moreover, the advantage thus gained by an early start leaves its mark upon their work throughout the season, enabling them to accomplish tasks which to some might seem impossible, and I opine that a vast amount of economical gardening may be successfully practised by working on the lines indicated.—LABOR OMNIA VINCIT.

white, the only colouring being a tinge of lemon in the throat, the combination being consequently the same as that in *Cœlogyne cristata*. It is an exceedingly beautiful one, and Mr. Wells must be esteemed fortunate in securing so fine and distinct a variety. *C. labiata alba* was placed before the Orchid Committee of the Royal Horticultural Society on December 13th, and awarded a first-class certificate.

#### ZYGOPETALUMS.

ACCORDING to the "Genera Plantarum," the genus *Zygopetalum* (sometimes written *Zygopetalon*) comprises about fifty species, including the plants known in gardens under the names *Bollea*, *Galleottia*, *Huntleya*, *Kefersteinia*, *Pescatorea*, *Promenaea*, and *Warscewiczella*. In gardens, however, the name is confined to a score or so of very handsome epiphytal Orchids from the warmer parts of America. They are characterised by stout pseudo-bulbs; large, strongly nerved evergreen leaves, leathery in texture and rich green, and erect scapes which spring from the base of the matured pseudo-bulbs, and bear several large showy flowers. The sepals and petals, which are much alike in size, shape, and colour, are partly united at the base, and spread in a peculiar fan-like manner; the lip is large, flat, and spreading. The disc is thick

and fleshy, and being ribbed or plaited has the appearance of a frill or ruff. The flowers are generally produced during the winter months, which greatly enhances their value. They supply a desirable colour among Orchids, the brown and green of the sepals and petals contrasting well with the blue and purple of the labellum. The flowers last a long time, and, unlike *Phalænopsis* and other winter-flowering Orchids, they are not affected to any great extent by fog.

Although epiphytes by nature *Zygopetalums* succeed best when grown in pots. These must be well drained, and the soil should consist of rough fibrous peat with a little sphagnum intermixed. A few lumps of charcoal may be added, and to these the roots will quickly make their way. *Zygopetalums* are often grown in the stove, but this treatment tends to enfeeble the constitution of the plants; with few exceptions they will succeed better in an intermediate temperature. During the period of growth a liberal supply of water is essential, and in bright weather slight syringings in the morning and evening are beneficial. They require abundance of sun and light, but should be shaded during the hottest part of the day. When growth is completed the supply of water may be gradually diminished, and in winter sufficient to keep the pseudobulbs from shrivelling is all that is required, though they must never be allowed to get quite dry.

*Z. BRACHYPETALUM*.—Sepals and petals short (as the name indicates), brown, streaked with green; lip white, veined with bluish violet; crest thickly striped with blue. A native of Brazil, introduced to cultivation in 1840, and exhibited before the Royal Horticultural Society in 1848.

*Z. BURKEI*.—A very distinct species, native of Guiana and Demerara. Exhibited by Messrs. Veitch, Chelsea, at a meeting of the Royal Horticultural Society in 1883. Sepals and petals green, thickly barred and spotted with brown; lip white with a crimson frill.

*Z. CLAYI*.—A garden hybrid between *Z. crinitum* and *Z. maxillare*, raised by Colonel Clay of Birkenhead about 1876. The large showy flowers are freely produced at various times of the year, according to the period of growth. Sepals and petals purplish brown, bordered with green, and with transverse bands of the same colour; lip rich violet-purple with a deeper coloured frill.

*Z. CRINITUM*.—A Brazilian species introduced in 1834. It closely resembles *Z. Mackayi*, and is figured in the "Botanical Magazine," t. 3402, as a variety of that species. The flowers are large, sepals and petals green, blotched and barred with brown; lip 2 inches across, creamy white with radiating blue or pink veins.

*Z. GAUTIERI*.—This is a native of Brazil, and was introduced in 1868. A very profuse bloomer, flowering as a rule in spring or summer. Sepals and petals large, green blotched and barred with brown; lip rich purplish blue with a deep velvety purple ruff. This species, of which there are several varieties, does well in a basket or raft.

*Z. INTERMEDIUM*.—A handsome free-flowering species introduced from Brazil in 1844. Perhaps the most useful and easily grown of all the *Zygopetalums*; too well known to require a detailed description here.

*Z. LINDENIÆ*.—A new and distinct species with narrow lanceolate acute sepals and petals of a light rose colour; the large ovate acute lip is white with numerous rose coloured veins. A native of Venezuela, introduced by Messrs. Linden and figured in "Lindenia," pl. 275, 1891.

*Z. MACKAYI*.—This, the oldest of the genus, was introduced from Brazil in 1825, and upon it Sir William Hooker founded the genus. It resembles *Z. intermedium* so closely as to be often confounded with it, and the latter may be met with in many collections under the name of *Z. Mackayi*. The flowers of the true *Mackayi* are, however, smaller than those of *intermedium*, and the lip is glabrous, while in *intermedium* the lip is more or less hairy.

*Z. MAXILLARE*.—A handsome species, the flowers of which are produced freely during the winter months and last for a long time either on the plant or in a cut state. The flowers are smaller than in most of the preceding kinds; the sepals and petals are green blotched with chocolate, the lip is nearly round, and is a rich bluish-purple.

*Z. ROSTRATUM*.—A well-known species with very large flowers, which differ considerably in colour from the majority of its congeners. It is a dwarf plant with a creeping rhizome, and succeeds best upon a raft or piece of Tree Fern stem. It flowers usually in late spring or early summer. Stove treatment is necessary for this species. The sepals and petals are white with greenish tips; the lip is white, with a few lines of lilac radiating from a crest of the same colour. Introduced from Demerara about 1830.

*Z. SEDENI*.—A garden hybrid between *Z. maxillare* and *Z. Mackayi*, raised in the nursery of Messrs. Veitch & Sons,

Chelsea. The flowers are large and showy; sepals and petals brown, with a narrow green margin; lip deep blue, with a rich violet frill.—A. B.

#### "THE ORCHID REVIEW."

THE first number of this new monthly publication has made its appearance, and if succeeding issues are similarly interesting, no doubt "The Orchid Review" will enjoy the patronage of a large number of Orchid growers. It is a convenient size, neatly bound in a slate-coloured cover, and contains thirty-two pages of well-printed letterpress. In addition to short paragraphs on various Orchids, the current number contains an account of "The Burford Collection," "Orchids of 1892," the first part of "The History of Orchid Hybridisation," "A Calendar of Operations for January," a report of the Orchids shown at the last meeting of the Royal Horticultural Society, and other matters of interest to orchidists. Illustrations of *Cypripedium* × *Niobe* and *C. × Edwardi* are given, with descriptive notes.

### HARDY FLOWERS.

#### SELECTIONS INVITED.

MR. SHANKS asks me on page 547 of your last volume to undertake a work for which I am not qualified. To take the initiative in the formation of a society is beyond me. Give me a good leader and I will follow him. If any friends interested in the subject, however, care to send me their opinions and ideas I will endeavour to tabulate them, and give to the readers of the *Journal of Horticulture* the general results arrived at. Some well-known florists have already communicated with me.

Will Mr. Page Roberts, Mr. Burrell, and others give us their lists of some of the best herbaceous plants for cutting from the last week in June?

The first twenty-four should be kinds suitable for exhibition purposes, say:—

(I.) The most useful twelve kinds;

(II.) The second best twelve;

and so on to forty-eight kinds, to include bulbous plants.

There are many who I know are anxious to "buy in" as soon as spring comes round, and will be very grateful for a little help in the selection of *varieties*, too, as well as *kinds*.—J. A. WILLIAMS.

[We shall be glad to forward any lists that may arrive at this office to Mr. Williams, also to publish the tabulations to which our correspondent alludes. Some communications on "Showing Hardy Flowers" must perforce be held over till next week.]

### WINTER BEAUTY IN BEGONIAS.

THERE was a little passage of arms between Messrs. Watson and Veitch at the Chiswick Conference on Begonias in summer, which appeared to afford considerable amusement to the audience. The latter was in the chair, and managed to condense so much valuable historical information into his introductory remarks that the Kew authority said he feared there was very little room for his own lecture, smilingly adding that he regretted it, because he thought it was rather the better. To this Mr. Veitch promptly responded that in that case he was very glad he had spoken first. Both interested their listeners unmistakably; indeed, the attention paid throughout the whole meeting was a sufficient indication of the interest that is now taken in the whole genus. The one regrettable thing was that time prevented Mr. Henry Cannell's contribution being taken, for he has so fine a collection of winter as well as summer blooming sorts, and presents them in such splendid condition, that any remarks from him on the best varieties and methods of culture could not have failed to prove valuable.

To say that the winter beauty which exists in Begonias is not sufficiently utilised would be something of a platitude. When we come to think about the matter, there are very few plants of which it could not be said with truth that they are not grown as much as they deserve to be. Of course they are not. There is some beauty or quality about almost every one of them, and beauty no more ought to be wasted than food. But if natural resources are boundless, human conveniences are finite, and we are driven, despite ourselves, to apply the law of the survival of the fittest. Too often it is not a question of what is to be selected, but of what is to be left out. There are the possibles, the probables, and the indispensables; the knotty problem is to classify the various claimants, so as to get in as many of the plants which "no garden, whatever its size, should be without," as can be grown well and creditably. The winter-blooming Begonias are in the transition stage. They have got beyond the possibles to the probables, and now they are struggling for admission into the charmed "indispensable" circle. It is not difficult to forecast the issue. Sooner or later they will win the day, and it only remains for those who

recognise the powerful nature of their claims to call attention to them whenever a word in season is likely to prove effective.

At Ascott I am told that Mr. Jennings grows the magnificent Gloire de Sceaux about as well and extensively as he does the Malmaison Carnations. If this be so they must present a sight the equal of which it would be difficult to find in the winter and spring, for a nobler plant there is not in the whole genus. Paterfamilias at the Swanley home of flowers is to be credited with its introduction, and it is one of the winter gems of his happy family. In a large house devoted to the winter-flowering section there the handsome foliage, not less than the charming flowers of this most beautiful plant, win the deepest admiration. In some spring notes on Woodstock Park, near Sittingbourne, I commented on the high place it holds in the estimation of that good gardener Mr. Dowdswell. There is nothing more effective there during the winter and spring. There cannot be the slightest doubt that it is one of the plants which have distinctly come to spread. The habit is admirable, the plant having a free open style of growth, and displaying its burnished leaves to the greatest advantage. The colour of the foliage is a point on which it is difficult to take a decided position. Reddish bronze would perhaps describe it the best, but however that might be it is both distinct and highly effective. Displayed amongst other plants it gives a warmth that is much appreciated in the cold dull season. It has "tone," as an artist would say. But the leaves are by no means the only effective part of the plant. The flowers, which are large and flat, are of a beautiful lustrous shining pink, a colour which, if not strictly fashionable, never fails to charm. If I might venture a word of advice to those who have a warm house to furnish in the winter, and wish its occupants to be select, I should say, Whatever your estimate of the Begonia genus as a whole may be put Gloire de Sceaux amongst the indispensables. There are two other dark-foliaged sorts fairly well known, Saturne and hydrocotilifolia. The latter is a very old friend, but Saturne is generally admitted to be a more effective plant, and though inferior to Gloire de Sceaux it has decided merit.

A green-foliaged Begonia of considerable value is undulata. It makes an admirable basket plant, and would, no doubt, look effective in a vase. The leaves are a deep green with a lighter margin, and the flowers are reddish salmon. Foliosa is hardly less valuable for the purposes suggested. Its leaves are small and dark green in hue, its flowers white with more than a mere suspicion of pink. This is a really good and graceful plant, well worthy of recognition. The variety Vernon or semperflorens atropurpurea is as useful for winter as for summer flowering, and its compact habit, free blooming, and pleasing bronzy leafage present a combination of attractions not easy to pass over. These are all as much esteemed for their leaves as for their flowers. Of these more particularly cultivated for blossom, nitida hardly needs a description, but it is too good to be excluded. Its variety alba odorata also merits a place, for, although the flowers are smaller than those of nitida, they are pure white and fragrant. It would be difficult to name two more useful sorts than these for winter work. Semperflorens gigantea carminea is effective in growth, its deep green leafage being distinctly striking, and its rich carmine red flowers being borne in great profusion. Odoratissima is another charming variety of the semperflorens group.

A winter Begonia which is not of very old standing, but which has well proved its claims for a place, is Carrièrei. This makes a delightful plant, not remarkable for great beauty of either foliage or bloom, but so full of flower under ordinary treatment as to win invariable admiration. Its easy management is a point not devoid of importance. Fuchsioides well merits its name, the clusters of beautiful pink flowers being both graceful and pleasing. Knowsleyana, silvery blush, has had its praises sung in the Journal more than once, and is so free growing and profuse in blooming that the present mention of it is not out of place. It makes an admirable plant, and is also valuable for cutting. Polyantha has flowers of a delicate pink shade, and they are very serviceable for sprays or even for working into buttonholes. Digswelliana is another pink that is now fairly familiar, but less so is Hybrida Wellsiana, which has drooping flowers of a pleasing red. Bijou de Gand is a pronounced midwinter bloomer, and bears its flowers in great profusion, while it is dwarf and bushy in growth. Insignis incarnata, lilac-pink; prestoniensis, rich orange red; Paul Bruant, pink; and socotrana, bright rose, are a valuable quartette. It would be easy to add to their number, for there are many others well worth mentioning, but there is often confusion rather than safety in numbers.

The feast of winter beauty which these plants provide is no meagre one; the question is their utilisation. The purposes they serve are numerous, and there are few establishments where no use could be found for them. Owing as we do a special debt of gratitude to all plants which give us brightness in the dull season, we ought to

look with special kindness on these Begonias, and there is much satisfaction to be found in the clear signs which exist of their growing popularity.—W. P. W.

#### IN MEMORIAM—MR. W. I. PALMER.

HORTICULTURISTS in Reading and the neighbourhood have sustained a very heavy loss in the death of Mr. William Isaac Palmer, one of the heads of the great biscuit firm. He passed away somewhat suddenly at the age of sixty-eight, and the occurrence came as a calamitous surprise to his thousands of friends, protégés, and admirers; for notwithstanding the fact that he closely approached the span of threescore and ten, he was a man of great vigour and had enjoyed robust health. We need hardly call special attention here to Mr. Palmer's life-long work in the cause of temperance or to the munificence of his public gifts, but it may not be out of place to mention the extraordinary extent of his private charity, the facts of which were sedulously kept secret during his lifetime, and have only come to light on the occasion of his death. He distributed a very large sum yearly unknown even to his intimate friends, and numerous poor widows in Reading were in receipt of weekly sums for assisting them in their struggle to live.

The deceased philanthropist—for such he was in the best sense of the term—was a great supporter of every movement for improving the condition and brightening the lives of the people. He took a special interest in horticulture, supporting the gardening societies in every possible way, and delighted in working in his own garden. At one time he was a very successful cultivator of Verbenas, while Pelargoniums, Roses, Chrysanthemums, and stove plants have all been grown exceedingly well at his residence, Hillside, Reading. Few men of culture and education were so broad in their tastes and sympathies as he. He closely followed the wonderful course of improvement in choice florists' flowers that has been going on in Messrs. Sutton & Sons' nursery for so many years, and while appreciating to the full their splendid strains of Primulas, Cyclamens, Cinerarias, Begonias, and other plants, was wont to say that he was still able to appreciate second class flowers. Modest blossoms in small gardens always won his admiration, and he was never weary of giving encouragement to all who endeavoured to add refinement to their lives of labour. At the funeral, which took place on Monday last, the leading firms, headed by Messrs. Sutton & Sons, closed their establishments, rich and poor alike mourning the loss of one whose exhaustless sympathy caused him to be looked upon as a friend rather than as a benefactor. May flowers shed their sweetest fragrance over the grave of one who loved them well, and strove to extend their influences far and wide.

#### PRICES AND QUALITY OF APPLES—CANKER.

I HAVE been waiting with some curiosity to see how Mr. Walter Kruse would extricate himself from the position in which his own words and his own figures had placed him. I took them as he gave them, without cavil or comment, giving him his own rope, so to say; but when the result showed that the average price of the Apples, of which Domino was one, was within a fraction of the figure, which in the case of his own fruit ("the finest and best packed" that ever went into the market) he admitted to be "very exceptional," he finds he has no time to go into the question, and must decline to continue the discussion. Considering that he found time to open it unsolicited, the pressure that compels this abrupt termination is not without significance. However, it is of no use my dwelling upon the matter further. I will therefore leave the subject, with the assurance to Mr. Kruse that I shall be only too happy to return to it should he care to wrestle another friendly fall with me when the present inroads upon his leisure have ceased. Perhaps I may add a recommendation that he should endeavour to spare a few moments for reading the letters from "A Yorkshireman" and "A Sussex Grower," on page 6; also those from Mr. Pearson and Mr. Molyneux, in the issue of December 15th. Further, I will add that I supplied to the Editor authority for every statement I have made as to the prices of Apples, from the 4s. 6d. per bushel Dominos to the £100 per acre Cox's; and the fact that those statements were allowed to appear may be taken as a proof that their accuracy is not questioned. I now send the sales bill of a London fruit broker, showing that the highest price obtained was 10s. and the lowest 4s. 6d., the nine varieties averaging within a fraction of 5s. 11½d. per bushel.

Turning to the question of canker, I have read the letters on the subject which have recently appeared with great interest. What Mr. Kruse has said about his soil and the applications made to it must have aroused the attention of many fruit growers, especially if, as in several cases on which comments have been made to me, it has been considered in connection with the remark in another letter, that his yearly manure bill for a farm of 40 acres amounts to £500. Most fruit growers agree with Mr. Tonks that the question of nutriment is at the bottom of many cases of canker, and it is important, therefore, that we should have detailed information as to the exact quantities of the different ingredients supplied in order to form a judgment that may be of practical value. In other words, I ask Mr. Kruse, in the public interest, to be good enough to tell us how his £500 a year is laid out. When he reflects that his answer may have an important bearing on the canker question which he has raised, and when I tell him that I also ask on behalf of one of the principal authorities on fruit in the country, I doubt not he will readily grant my request.—W. P. W.

## NATIONAL ROSE SOCIETY.—JUDGING.

YOUR correspondent E. R. Shanks (*Journal of Horticulture* pages 554-5) I suppose writes under a *nom de plume*, as his name is not on our list of members for 1892. I was much amused at his letter; in parts it is quite comic, although possibly written quite seriously.

I do not come under Mr. Shanks' category of "clergymen" (although the son of one who was not a rosarian), "lawyers," "doctors," "intelligent tradesmen" (I wish I were one), or even growers of Roses for trade purposes; but I have been a Judge for some years at our N.R.S. meetings, as well as at Croydon, Reigate, Sutton, Windsor, and this year at Earl's Court and elsewhere. I do not think that we have any judge at our meetings who is so small a grower as Mr. Shanks mentions of—"300 or 400 plants." Nor can I agree with Mr. Shanks that the fact of growing a small number of Roses thereby debars a rosarian from having the judgment requisite to tell whether the Roses in a big class are good or not; but the fact is and always has been, that the large amateurs' classes are judged by "big growers" amongst the professionals, and in the same way the professionals' large exhibits are judged by the amateurs of greatest experience and who grow a considerable number—more like 2000 or 5000 than 300 to 400.

The selection of the Judges for these big classes is our first care, as we who are members of the N.R.S. Committee know how very important it is that the judging should be accurate. A professional Rose grower's career may be made or marred by successful exhibiting or the reverse, and I think I may confidently state as instances that the very great reputations of both Messrs. Benjamin Cant and Frank Cant have been partly made and much helped by their superb exhibits on very many occasions; also that such exhibits as other professionals this year have placed in evidence, notably those of Messrs. D. Prior & Son (of Colchester) at Croydon, and of Mr. Merryweather (of Southwell, Notts) at Chester, have brought them more prominently to the front; also that the reputations of great hybridisers like Messrs. Dickson of Newtonards, Ireland; Mr. Wm. Paul, and Mr. George Paul are maintained and enhanced by their victories and the numerous first class awards and medals gained at our N.R.S. Exhibitions. With the knowledge of these facts our judges are (to the utmost of our power and with the selection of such names as are at our disposal) most carefully arranged, and the best men possible decide the prizes in the classes they are supposed to be the best judges of and have had special experience in.

In regard to the Chester matter cited, the delay mentioned was on that occasion of absolutely no importance. My reason for saying so is that the day was a miserably wet one, and the flowers did not suffer by the delay. Moreover, any blame should fall on the shoulders of those deserving it, and that is on the Committee at Chester, who mismanaged the Show, and thereby delayed the opening and judging. I was one of those who "critically examined" the new varieties, and I may say that, as far as I can recollect the matter, the opinion of the majority had been expressed before one o'clock, and if any fault could be found in this particular case, it was in the fact that there were too many judges, and part of the delay was caused by the over-anxiety of one gentleman to have everybody's opinion, which fact alone unduly prolonged the period of judging which Mr. Shanks complains of.

It is the idea of some people that the bigger the grower the greater the opinion, and I think Mr. Shanks partly falls in with this view, but I do not agree with it, and I cannot see why a good medium-sized grower, or even a small practical grower of Roses for exhibition, should not be quite as good a judge as a grower of 3000 or 10,000 Roses. I may say that, from my own experience of Rose Show judging, I could instance several of the smaller growers who are infinitely superior in the quality of discrimination as regards the merits of Roses than many of those who grow their thousands. One reason for this superior expert knowledge is that an intelligent rosarian who has a comparatively limited number knows the merits and failings of all the Roses he grows, and that an exhibitor (our judges being taken from the best available of that class alone) usually grows only the best varieties, such Roses being the kinds shown at our meetings by the members who win our prizes.

## CRYSTAL PALACE ARRANGEMENTS.

In reference to "W. R. Raillem's" well thought out remarks in your last issue (p. 4), I should like to say a few words. I am in agreement with him that the arrangements at the Crystal Palace are not at all sufficient to the requirements of our members' exhibits. There is no good reason for this failing on the part of the C.P. executive, as the time given between the closing day for entries and the meeting are quite sufficient to allocate properly the spaces for each class. As your correspondent pertinently puts it, any small societies would hear a good deal of complaint if their affairs were as inefficiently managed as the arrangements of the C.P. were at our meeting in 1892. But the question, I think, is even larger than this, as one would almost require to train specially (as matters now are at the C.P.) to run "100 miles in 100 hours" to cover the distance one has to get over when you exhibit in several classes.

## THE PROVINCIAL SHOW.

I hope "W. R. Raillem" is right in his belief that there is "more money" at Workshop than in East Anglia. I doubt it; but those responsible at Workshop will no doubt be equal to the occasion, and will produce the inevitably necessary coin. But surely a cathedral city could be found for a provincial show in East Anglia which would meet your correspondent's difficulty another year; and, as far as I am personally concerned, I should like on all subjects possible (outside the suggested new change of date for our Metropolitan Show) to meet the views of those to whom I am at times opposed, even at the sacrifice of some personal advantage.

## THE PROXY QUESTION.

"W. R. Raillem" has very properly said that there was no argument used at our meeting against this proposal except that of trouble to the secretaries. I should not dream myself of giving unnecessary trouble to those gentlemen, but if that be the only difficulty I can hardly see that it is a proper answer to this proposed concession which it is suggested should be made to country members who cannot attend our meetings. As I mentioned at the meeting, either side might be surprised at the result of the use of proxies; but I may remark that there are several, perhaps many, ladies members of the N.R.S., and they seldom grace (I believe that is the correct expression) our meetings with their presence. Ladies are not always shy, but they have a natural disinclination to go where they would be in a very small minority. For them voting by proxy would be a boon, and I know that there are several who take as great an interest in the welfare of the National Rose Society as any of the sterner members; moreover, they are keen judges of good Roses, and in fact there is one lady who helps our Executive yearly in that capacity; also as regards arrangement, colour, and form, we men are really "not in it" with them. For this portion of our Society proxies would be a desirable concession, and also for members in remote districts like the north of England, Scotland, and Ireland.

## DATE OF METROPOLITAN SHOW.

I am quite confident that whichever side is conclusively proved to be right in the next few years in regard to the date of the Metropolitan Show—and both sides will have dates to favour them from 1893 to 1898—will be able to win over the doubtful members, or those not keenly or personally interested in the question. In the interval, I think the matter would better be left to rest undisturbed, as it is one which is not conducive to "good blood." The fact of the supporters of later dates having such fixtures as July 7th, 6th, and 4th, in 1894-5-6, should reconcile them to the position of letting facts prove or disprove their case, otherwise the question will become anything but conducive to *bon camaraderie*, and, if annually reproduced, be more a nuisance than an advantage to the Society.

I would like to say in conclusion that, although the "National Rose Society" is not progressing "by leaps and bounds," it is steadily and even comparatively rapidly progressing. This year, for the first time in its history, it has passed the 500 in the roll of its members, and if we all would unite by personal efforts, the financial position could easily be made to appear most flourishing.—CHARLES T. GRAHAME, *Croydon*.

## THE MEDAL ROSE.

As one of the medal Judges (not *the* medal Judge) at the N.R.S. Exhibition, may I say one or two words? I cannot agree with Mr. Raillem that the medal Rose is necessarily a proof of the excellence or otherwise of an exhibition. One swallow does not make a summer, and one Rose does not make or condemn an exhibition. I think it was the general opinion of rosarians that the last Crystal Palace (N.R.S.) Exhibition was an average one, although there was no H.P. of superlative excellence. The Judges may have been wrong, but it was their unanimous opinion that the Gustave Piganeau to which the medal was awarded was the best representative bloom of the H.P.'s. I may, perhaps, be allowed to say, that although we were fully aware that the centre of the bloom was not quite perfect, yet we could not describe it as a flower which "had a decidedly split centre." But I am glad to be entirely in agreement with Mr. Raillem that there is much need of reform in judging the medal Roses. I should much like to see the medal withheld if there were no flower of great excellence. This is the rule as to seedling Roses—why should it not be the rule as to cut blooms? (Other improvements which have been suggested would be valuable, but this is one which I should much like to see carried out. In conclusion I would like to say that I hardly think there can be found three men who desire the post of awarding the medals at the N.R.S. or any other Exhibition. The duty is one which no one covets, but which is undertaken in loyal obedience to the orders of the Secretary. It is a work of great importance, and one which should be carried out only by rosarians of great experience. It will be said that there is other work for them to do. Quite so. But let the medal judging be deferred until the general judging is over, and then I fancy that many a bloom which has been held together by worsted will have shot its ephemeral bolt, and the true lasting flower will gain its reward.—HENRY B. BIRON.

## THE ROSARIAN'S YEAR BOOK.

THIS annual, so welcome to rosarians, is just issued. It contains an excellent portrait of its editor, Rev. H. H. D'Ombrian, with appreciative notes historical and floricultural by the Very Rev. Dean of Rochester,

the Revs. H. A. Berners, F. R. Burnside, and J. A. Williams, with Messrs. John Harkness, Edward Mawley, George Paul, and W. H. Williams form a symposium and chat on "Tea Roses" pithily, usefully, and agreeably. The Editor discourses on "French Rosarians" and the "National Rose Society," Mr. Charles Grahame on the "Deterioration of Roses," while Mr. Alexander Hill Gray continues his cheery "Jottings." Mr. Mawley has the closing chapter, as usual, on "The Weather of the Rose Year," in which so much careful observation is displayed. A casual glance through the pages shows that there is plenty of variety in them—plenty of valuable matter and good reading for a shilling. So now let all who love Roses buy the book and be happy, for they can scarcely be completely so without it. It is published by Bemrose and Sons, London and Derby.

[A very interesting letter from Mr. Henry V. Machin, Gateford Hill, Workop, will be published next week.]

### CANKER ON FRUIT TREES.

MR. WALTER KRUSE, in his communication (page 564, December 29th, 1892), loses sight of the fact that those scientists who have investigated this subject consider canker a disease of fungoid origin, consequently only produced indirectly by the composition of the soil in which affected trees happen to be growing. Indeed, it is a question whether the presence of one infected tree in a garden or orchard is not more conducive to the spread of this malignant disease than any quantity of iron oxide or other chemical usually found in mother earth, for from every cankerous growth spores are thrown off in quantity, germinating wherever they effect a lodgment, owing to defects in the bark, and quickly producing those excrescences we unfortunately know too well.

Directly remedial measures have therefore been recommended in preference to indirect ones, scraping and paring the parts attacked, to be followed by liberal applications of paraffin oil or other powerful antiseptic during the months of May and June, when the fungoid growth is most active, being the proposed cure. Those who have advised this method of combatting the pest believe that if energetically pursued year after year it would in time result in the diminution, if not complete extermination of the disease. Has Mr. Kruse tried this remedy?—B. D. K.

MR. KRUSE does well in directing attention to this tantalising and hackneyed subject (*Journal of Horticulture*, December 29th, 1892, page 564). His case is very clearly and plainly stated, except that part where he says, "Apples and Pears are liable in a certain soil (of which an analysis is given) to canker, and Cherries to gum; Plums, Gooseberries, and Black and Red Currants do well." This refers to matters of fact, and may not be (nor are they) questioned; but the statement appears, to me at least, ambiguous, or to imply that because Apple and Pear trees canker and Cherry trees gum in "a certain soil," some analogous disease ought to be expected to infect the Plums, Gooseberries, and Currants, if canker and gum are due to external cause, that is, caused by the attacks of parasitic fungi. This is the other side of the question—What is the cause of canker and gum? Mr. Kruse does not allude to the possibility of these diseases being due to the direct cause and action of parasites, but is strictly empiric, and attributes canker and gum to predisposing cause—excess or deficiency of soil constituents. Predisposing causes—heredity and environment—are no doubt the "root" from whence parasitic infestations spring. Animal or vegetable parasites, however, will attack and thrive if let alone on any and every plant that supplies them with their essential food. That is the point; attack on the one hand, resistance on the other hand, is Nature's undeviating law, and the "weakest go to the wall"—the plethoric and the starved. In this we have the "survival of the fittest;" that plant which becomes located where the soil and environment is best suited to its requirements will thrive the best and longest. So far I cordially agree with Mr. Kruse and the empirics. Cultivators, however, ought not to act on empirical lines, but, like the "boards of health," should take care to remove the predisposing causes of disease, and so safeguard their cultures against attacks or lessen the malignity of parasitic infection. This can only be done by a thorough knowledge of the disease and its origin.

Now, canker on Apple and Pear trees does not infect Cherry, Plum, Gooseberry, and Currant trees, nor any species of *Cerasus*, *Prunus*, or *Ribes*, but is found on Ash, Elm, Oak, and many other trees. That is one reason why "Plums, Gooseberries, and Black and Red Currants do well" where "Apples and Pears are liable to canker"—namely, different plants are subject to different diseases, and have no connection whatever with soil constituents beyond that required in the host for the growth of the disease. Nevertheless a fungus of the same genus as the canker fungus is often found on the dead twigs or branches of Currant and Gooseberry bushes, and is very interesting and beautiful. Almost any small branch or twig which has been lying on the ground in a damp situation a year affords specimen in November, when "the whole surface of the twig is covered from end to end with bright pink prominences bursting through the bark at regular distances, scarcely a quarter of an inch apart. Towards one end of the twig probably the prominences will be of a deeper, richer colour, like powdered cinnabar. The naked eye is sufficient to detect some difference between the two kinds of pustules, and where the two merge into each other specks of cinnabar will be visible on the pink projection. By removing the bark it will be seen that the pink bodies have a sort of paler stem, which

spreads above into a somewhat globose head, covered with a delicate mealy bloom. At the base it penetrates the inner bark, and from it the threads of mycelium branch in all directions, confined, however, to the bark, and not entering the woody tissues beneath. The head, placed under examination, will be found to consist of delicate parallel threads, compacted together to form the stem and head. Some of these threads are simple, others are branched, bearing here and there upon them delicate little bodies, which are readily detected, and form the mealy bloom which covers the surface. These are the conidia, little slender cylindrical bodies rounded at the ends.

"Passing to the other bodies, which are of a deeper colour, it will soon be discovered that, instead of being simple rounded heads, each tubercle is composed of numerous smaller, nearly globose bodies, closely packed together, often compressed, all united to a base closely resembling the base of the other tubercles. If for a moment we look at one of the tubercles near the spot where the crimson tubercles seem to merge into the pink we shall not only find them particoloured, but that the red points are the identical globose little heads just observed in clusters. This will lead to the suspicion, which can afterwards be verified, that the red heads are really produced on the stem or stroma of the pink tubercles.

"A section of one of the red tubercles will show us how much the internal structure differs. The little subglobose bodies which spring from a common stroma or stem are hollow shells or capsules, externally granular, internally filled with a gelatinous nucleus. They are, indeed, the perithecia of a sphaeriaceous fungus of the genus *Nectria*, and the gelatinous nucleus contains the fructification. Still further examination will show that this fructification consists of cylindrical asci, each enclosing eight elliptical sporidia, closely packed together, and mixed with slender threads called paraphyses.

"Here, then, we have undoubted evidence of *Nectria cinnabarina*, with its fruit, produced in asci growing from the stroma or stem, and in intimate relationship with what was formerly named *Tubercularia vulgaris*. A fungus with two forms of fruit, one proper to the pink or *Tubercularia* form, with naked slender conidia, the other proper to the mature fungus, enclosed in asci and generated within the walls of a perithecium. Instances of this kind are now known to be far from uncommon."—(Fungi, Cooke and Berkeley, page 193).

The foregoing comprehensive extract depicts the fungus, *Nectria cinnabarina*, found on Gooseberry and Currant twigs or branches detached and laid on damp ground, also on dead twigs or branches on the bushes. The fungus is also common on stakes of Ash, Maple, Sycamore, and other trees used in mending gaps in hedges. Anyone, therefore, can readily see how a fungus may and does cause the bark to peel off a dead twig or branch, and hang in rags. This the fungus effects by living on and abstracting the substance of the inner bark, so that the bark is separated from the wood, which remains, so far as this fungus is concerned, intact, but exposed to the destructive effect of the weather, and to the inroads of other fungi. *Nectria cinnabarina* will not live on living twigs, for if we put in a stake of a Currant, and the upper or any part of it die, the dead part only affords a fitting soil and a peculiar food for its growth, health, and reproduction.

Now, the fungus *Nectria ditissima* causing canker in Apple and Pear trees, acts similarly to *N. cinnabarina*, with a material difference—namely, it lives and feeds on the living inner bark of Apple and Pear trees, also Ash, Beech, Elm, Mountain Ash, Oak, and other trees. It is not of internal, but of traumatic or wound origin, for its germs cannot pierce sound healthy bark, clean, dense, and elastic; but when the bark is injured by hailstones, sun and frost cracks, punctures of insects and burrowing of larvæ, pecks of birds, bites and scratches of animals, breaking of twigs and erosion of bark by wind, bruises, abrasions, and manipulations, then the spores of the fungus gain access to the inner bark by the wounds, one or all, and set up canker by living on the alburnous tissues, its peculiar food. That is all that is wanted to produce canker on Apple or Pear trees—the wound and the spore of the fungus. When the spores gain access to and become "seated" in the wound they germinate, push their mycelial threads through the live portions of the bark, cambium, and alburnous tissues, living on and abstracting their substances, which causes the bark to die, become fissured and scaly, accompanied by a considerable swelling of the surrounding tissues, forming an unsightly excrescence. Thus established the fungus strives to enlarge the wound, which the tree resists by throwing out an excessive callus around the circumference of the wound, thereby striving to expel the fungus, cover the wood with new bark, and so secure itself against further attacks. But the battle is never in doubt, the fungus always proving the victor. Young shoots and small twigs are encircled in the year of attack, young plethoric trees feed it best and succumb the soonest, sturdy trees and large limbs resist it best and longest, whilst aged trees continue the battle many years, during which they are pitiful unprofitable objects. The mycelium of the fungus extends only in spring and summer, when its food, the sap, is active and cambium abundant, its "fruits" being produced in late autumn, and during the winter it is quiescent.

The attacks of the fungus are not confined to poverty-stricken or aged trees, though it is most malignant on crowded trees in neglected gardens and orchards, yet it has a penchant for young trees and new varieties. Heredity is beside the question, and constitutional susceptibility not well defined; yet some sorts of Apples and Pears have such dense or elastic bark and vigorous healthy constitutions as to resist or throw off cankerous affections. Notwithstanding all cultural effort and selection there are no varieties of Apple or Pear that in all conditions of

climate, soil, and culture are canker-proof. Therefore we are left face to face with the fungus which claims 75 per cent. of the trees in some orchards and not less than 6 per cent. of the trees under the best cultivation as its victims.

Inducements of canker on Apple and Pear trees are crowding and neglect, sticking them in holes in hard soil and stubborn clay, land stagnated with water, arid sand and sterile gravel, a thin crust of soil over chalk, titillating the surface instead of breaking up the hard impenetrable pan chokeful of iron oxides and corroding acids, rich loose soils, low situations, bleak sites, exuberant growth, and improper culture or none. Over these the grower has complete control; therefore, assuming canker to be a preventible disease, it is the cultivator's own fault if the trees are not free, for it is easy to thin crowded trees, clean them, and supply manure. To plant the trees properly in well prepared ground drain waterlogged land, avoid sandy gravelly brash (the greedy maw of chalk), break up pans, render loose soils firm, eschew low and bleak sites, check exuberance by root-pruning, and practise good cultivation all round.

But Nature has to be reckoned with—chills in spring; frosts injuriously affecting the sap vessels; a wet, cold, late season; sappy immature growth liable to damage by severe weather, all aid canker, the admittance of the fungus spores into wounds caused by hailstones severe frosts, and summer heat. How, then, are we to avoid canker? Every empiric has some panacea. Is canker less prevalent now than it was in Shakespeare's time, when it was referred to in almost all plays by the immortal universal tongue? Are the orchards of Albion as fair and prosperous now as at the middle of the current century? I trow not. Look around, and almost everywhere may be seen more decrepit than flourishing orchards, and markets mainly supplied with cheaper and better imported Apples and Pears than the home grower does produce.

Canker has done this. It has, combined with neglect in not planting young, clean, healthy trees in fresh properly prepared soil, with a suitable site, so as to form an orchard that would produce fruit up to the requirements of the time—clean and bright in skin, even in size, and of good using qualities, either for dessert or culinary purposes, by the period the old orchard trees were worn out. What is the remedy? Half a century's experience has convinced me that there is practically but one cure for canker in old orchards—the destruction and burning of the trees branch and root as soon as possible. If the trees are not very old and their stems are sound, it may be worth while to cut off their heads and regraft them with varieties that are found most free from canker, if not entirely so, afford the best crops and bring the most money from the salesman. But it is no use getting young healthy heads on old orchard trees without providing food in the soil for the support of their crops, otherwise the trees will soon cease to bear fruit satisfactorily.

How to cure trees of canker is very simple, indeed as plain as a pikestaff—destroy the fungus and all will be well, not otherwise. No cultivation whatever will render Apple or Pear trees canker-proof. We must do with them as the timber merchant does with that he wants to save from "dry rot" (or any rot), charge its pores with some substance that will prove fatal to any fungus spores that alight upon it. That is the physician's medicine—kill the germs, eliminate the virus from the system, and the patient recovers. Empirics oftener miss than hit the mark, but the experienced practitioner never fails to afford some relief, if not effect a perfect cure. I have tried almost every "patent" for canker—all worthless, time, labour, good land wasted. The fungus, *Nectria ditissima*, "laughs up its sleeve" and prospers, never better than at the present time, for, notwithstanding all our assumed supremacy, we are, as regards parasitical infestions, far behind our continental neighbours and kinsmen in America and at the Antipodes.

It is no use blinking at canker, there it is—scarcely an orchard free, yet nurserymen raise millions of trees, free from speck or blemish, and they are planted throughout the length and breadth of the land, where they fall prey to canker and neglect. How does the nurseryman keep his trees free from canker? By the only way, not having a cankered tree on the spot. Whenever there is a speck of canker off goes that branch and into the fire. I am aware that it is not so in all cases, but I have never seen a cankered tree in any of the large nurseries, and never have received an infected tree from any. There we see them by the million with the current year's wood as thick in degree from the little finger to the thumb without any cankerous affection. Why? Their culture is of the best, land well tilled, judiciously manured, not a canker spot allowed to mature the spores of the fungus and infect the whole neighbourhood; but there is not an orchard of a dozen years' growth in which there is not some canker, and instead of rooting it out it is left to its way, and the whole plantation becomes a wreck before the trees have arrived at full profit. That is the way to grow fungi, not Apples and Pears. It is impossible to grow "two" crops. If canker infest a tree the fruit is worthless, for the fungus lives on the very substance that is necessary for the support of the Apple and Pear and the formation of buds and healthy growths for the production of profitable crops. This may be poor consolation for persons with cankered orchards, and they will perhaps not thank me for these outspoken remarks. No matter; there are some that are "sick" and need a physician to cure their Apple and Pear trees of canker. I will tell them how to do it, if assured that the ground is properly sanitated (drained), the situation healthy, the dietary generous, and cleanliness strictly regarded. If not, these things must be seen to at once, for they are the best safeguard against disease, restoration to health, and its preservation.

Cure for Canker.—1, When any tree shows a canker speck or cankered wound, cut it off and burn it. This should be done not later than October. It will not do to leave it on the tree until early spring, for its "fruits" will have been cast before that time, or there is danger of scattering them about. Therefore, if the tree is to have a new head put on in the spring by grafting, cut it down in the autumn, and consume the cankered parts by fire. 2, Cut off the heads of all cankered trees, and regraft them with varieties that have proved free from the affection. 3, If the tree is young and cankered in the stem cut away the cankered part during summer clean off, that is, just outside the swelling, and evenly and neatly all round, and cover it at once with a plaster of cow manure and clay, and over that a piece of sack to keep it from falling off. Before the autumn the bark will have healed around the wound without any abnormal swelling, but a steady and healthy growth of new bark will be formed for covering over the wound. If the wound still swells abnormally cut it still further and outside the swelling, which remove carefully with a chisel, then apply the plaster. Make no mistake—the canker—the fungus must come out, or no cure can be effected. 4, Spray the trees in February or as soon afterwards as the weather is mild, always before the buds cast their scales, and in dry weather, with modified Eau Celeste, made by dissolving 2 lbs. of sulphate of copper in one vessel, 2 lbs. of carbonate of soda in another, pouring together and adding 1 pint of ammonia (20°), and 32 gallons of water, using a Vermoral Knapsack Pump, and let every part of the tree be coated with the spray, then no fungus can push its germinal tube on that tree without absorbing its last meal. It is good against "Apple scale" and "cracking in Pears," but these require to be coated with the fungicide as soon as the fruit is well set in each case. The spraying need not be repeated to prevent canker, once a year being sufficient, and always before the spores have pushed their germinal tubes into the inner bark, otherwise the spraying is useless, for nothing will destroy the fungus then without killing the trees.

The foregoing is all I know about *Nectria ditissima*—its prevention and cure. It is necessary to state that what is often taken for canker is not that caused by the fungus, for a tree may have wounds without *Nectria ditissima* penetrating the inner bark around the wound, they being entirely innocent of canker caused by fungi.

If the wounds are free from *Nectria ditissima* there will not be any abnormal swelling of the bark around the circumference, but a clean growth of new bark extending over them, in which assistance may be given by a plaster of cow manure and clay over each, and it will keep out *Nectria ditissima* spores.

Apple and Pear trees are sometimes affected by a dry gangrene, caused by frost or improper nutrition—excess or deficiency of soil constituents, and as this and cankered trees may be assisted to cover the wood with new bark and resist fungal attack better by manurial applications. Mr. Kruse's case will be further referred to in another communication.—G. ABBEY.

EVENTS OF THE WEEK.—A meeting of the Royal Botanic Society takes place on Saturday, January 14th. The Committees of the Royal Horticultural Society also meet for the first time this year at the Drill Hall, James Street, on Tuesday, the 17th. On the same day at 3 P.M. the annual general meeting of the Gardeners' Royal Benevolent Institution will be held at Simpson's, 101, Strand, W.C., particulars of which are given elsewhere. A gathering of the Horticultural Club and a Committee meeting of the National Rose Society will likewise take place on Tuesday afternoon at the Hotel Windsor, Victoria Street, S.W.

— THE WEATHER IN LONDON.—There has been a change in the weather in the metropolis since last week. On Sunday it rained, more or less, nearly all the day, and on Monday also rain fell heavily during the afternoon and evening. Tuesday proved fine and comparatively mild, local showers occurring during the afternoon. On Wednesday morning frost was apparent, and at the time of going to press it is fine, but cold, with a north-easterly wind.

— WEATHER IN THE NORTH.—The week ending the 10th inst. has been throughout of a very wintry nature. Snow fell over the country generally, in some places to the depth of nearly a foot; and for a second time this winter we had 24° of frost. Lower readings are reported farther north. Towards the end of the week a thaw took place, but we have 10° frost on Tuesday morning.—B. D., *S. Perthshire*.

— APPLES FROM CANADA.—It may interest your readers to know that 470,380 barrels of Apples have been shipped from the port of Montreal to the United Kingdom during the season that has just closed. This is an increase of 157,043 over the season of 1891.—C.

— **WEATHER AT LIVERPOOL.**—We have again had a very severe week with a heavy fall of snow, the whole country being completely covered in its wintry garb. The weather has been intensely cold. A slight thaw took place on Saturday, and continued over Sunday. A change will be eagerly welcomed.—R. P. R.

— **MR. G. A. DICKSON.**—We are pleased to learn that Mr. George A. Dickson, sen., of the old and well known Chester firm, now trading as Dicksons, Limited, has been placed on the Commission of the Peace for the county of Cheshire. For some years Mr. Dickson has been a magistrate for Chester, and was Mayor in 1885–1886.

— **LONDON PANSY SOCIETY.**—This newly formed Society will hold its first Exhibition at the Drill Hall, James Street, Westminster, on June 6th, in conjunction with the meeting of the Royal Horticultural Society. The schedule, which is included in the Royal Horticultural Society's arrangements for the current year, is comprehensive, there being no less than twenty-eight classes.

— **HORTICULTURAL EXHIBITION AT ISLINGTON.**—A large Exhibition of plants, flowers, vegetables, fruit, plant houses, heating appliances, and horticultural sundries will be held, under the auspices of the Royal Horticultural Society, at the Agricultural Hall, Islington, N., on August the 29th and the three following days. Prizes to the amount of £400 are to be offered, and the schedule will be issued by the Society about the end of March.

— **ROYAL METEOROLOGICAL SOCIETY.**—The annual general meeting of this Society will be held at 25, Great George Street, Westminster, on Wednesday, the 18th inst., at 7.15 P.M., when the report of the Council will be read, the election of officers and Council for the ensuing year will take place, and the President (Dr. C. Theodore Williams) will deliver an address on "The High Altitudes of Colorado and Their Climates," which will be illustrated by a number of lantern slides.

— **THE LARGE BUNCH OF GRAPES.**—A correspondent writes:—"Allow me to state that Mr. Dickson's bunch of Grapes, shown in your issue of December 29th (page 572), not only weighed 26 lbs. 8 ozs. when cut, but would have weighed that at the Show had someone not cut one of the leading points of the bunch the night previously; therefore I have no hesitation in saying that the Arkleton bunch was not only the largest, but the heaviest single bunch on record. I had charge of the vineries at Arkleton, and know what I say is true."

— **THE WEATHER IN STIRLINGSHIRE.**—Another week of very wintry weather; the mean maxima 32°, the mean minima 18°. The frost of Thursday afternoon was very intense. At 3.30 the mercury indicated 21° of frost; it continued falling until about 6.30, when 29° of frost were recorded. Afterwards it gradually rose until next morning when the maxima thermometer was standing at 24°, the highest for the twenty-four hours. A good deal of snow fell on Friday and Saturday, but a thaw set in on Saturday night, and is still continuing, so that by Monday afternoon the snow had nearly disappeared.—G. McDougall, *Stirling*.

— **THE NORTH GALLERY.**—The fifth edition of the official guide to the "North Gallery" at the Royal Gardens, Kew, has just been issued, and a copy should be in the hands of all who are interested in the magnificent collection of beautiful paintings, executed by the late Miss Marianne North. The gallery contains upwards of 800 pictures representing plants, trees, and flowers of nearly the whole civilised world. Detailed botanical and historical descriptions of the paintings are given in the Guide, as well as notes referring to the woods forming the panelled wainscot below the pictures. In addition there is a biographical notice of Miss North, and much matter of interest to gardeners, forming in all a neat volume of 160 pages for the modest sum of sixpence.

— **THE WEATHER LAST MONTH.**—December was a cold month with much frost, especially during the last week, but with a fair amount of sunshine, fourteen days being bright, and two of them were also clear. Barometer—highest reading 30.30 at 9 A.M. on the 16th and 28th; lowest 29.34 at 9 P.M. on 11th. Total rainfall was 1.03 inch, which fell on thirteen days; this is 1.30 inch below the average for the month. The greatest daily fall was 0.28 inch as snow on the 8th. Highest shade temperature, 54° on 15th; lowest, 13° on 26th. Lowest on grass, 7° on 26th and 27th. Mean daily maximum, 40.29°; mean daily minimum, 27.87°. Mean temperature of the month, 34.08°. Wind was in a westerly direction twenty-one days. The garden spring ran 20 gallons per minute on the 31st.—W. H. Divers, *Ketton Hall Gardens, Stamford*.

— **THE CALIFORNIAN SEQUOIAS.**—The United States Government is taking measures to save the remaining giant trees of California, the majestic Sequoias. Some of these are believed to be upwards of a thousand years old.

— **COTONEASTERS.**—In the gardens at Holly Lodge, Highgate, I recently noticed some fine bushes of Cotoneasters that were covered with red berries. The branches were laden with hoar frost, and this formed a striking contrast to the fruit.—H.

— **LEE, BLACKHEATH, AND LEWISHAM HORTICULTURAL SOCIETY.**—The annual meeting of the above Society was held at the Working Men's Institute, Old Road, Lee, on Monday, January 9th, 1893. The chair was occupied by John Penn, Esq., M.P., the President.

— **DOUBLE PRIMULAS.**—Messrs. John Laing & Sons, Forest Hill, send us blooms of Marchioness of Exeter (white), A. F. Barron (pink), Annie Hillier (blush), double Primulas. They are full and symmetrical, but the prolonged fogs, we are told, are fast despoiling the plants of their beauty.

— **PRIMROSES AND POLYANTHUS.**—These succeed best with me, whether in the open ground or in pots, if they receive a rich surface dressing of well decayed manure, and those persons who find that manure dug in the ground injures the plants might try the top-dressing.—AN OLD GROWER.

— **LYCHNIS VESPERTINA FLORE-PLENO.**—Some people fail entirely to strike cuttings of this beautiful Lychnis. I am successful by taking cuttings early in May with a heel, or close from the stem, and inserting them in the open ground, protecting them with a cylinder of glass; a bottomless honey jar or lamp chimney answering the purpose well.—W. T.

— **OLD PEOPLE'S GATHERING.**—The Astwood Amateur Gardeners' Society were instrumental in carrying out a most successful gathering of the aged and widows of the neighbourhood on the 30th ult., this being the third annual gathering. About one hundred sat down to a substantial meat tea, and a large quantity of "fragments" were distributed on the following day to the needy. These gatherings are looked forward to as the happy day of the year, when all combine to make it a success. Addresses, music, songs, recitations, and a dance to finish were included in the programme. May the example become contagious through other localities.—J. HAM.

— **WOODFORD HORTICULTURAL SOCIETY.**—A meeting of this Society was held on Tuesday, 9th inst., at the Wilfred Lawson, Andrew Johnston, Esq., J.P., presiding. A paper was read by Mr. G. Laing Paul of Cheshunt, entitled "Apples for Private Gardens." The essay proved very interesting, and was much appreciated by the numerous audience present. An interesting discussion ensued, to which Mr. Paul ably replied. A collection of Apples, staged by the members, added to the interest of the meeting. The essayist was accorded a hearty vote of thanks for his paper, and a similar compliment to the Chairman terminated the meeting.—J. B. RIDING.

— **THE INTERNATIONAL HORTICULTURAL EXHIBITION OF 1892.**—I am sorry to find that very unwillingly I did an injustice to a very energetic worker in all horticultural matters—Mr. Richard Dean—for wherever there is work to be done that affects horticulture he is sure to be found. In mentioning, then, Mr. Marshall as the moving spirit in these Exhibitions, I found that I only looked at one side of the question. Mr. Marshall had everything to do with regard to the judges, and as I was a judge and not an exhibitor I unthinkingly regarded him as "boss," but as Mr. Dean had the very arduous work of arranging the Exhibition, and all can testify to the admirable manner in which it was carried out, making one wish that on some occasions we might have the benefit of his long experience.—D., *Deal*.

— **DEVON AND EXETER GARDENERS' ASSOCIATION.**—The first of what it is proposed to make an annual supper of the Devon and Exeter Gardeners' Association took place on Friday evening, January 6th, at the Turk's Head Hotel. There were about fifty members present. The chair was occupied by Mr. Hope (Messrs. Veitch & Son), the vice-chairs being filled by Mr. T. C. Bartlett (head gardener to Lady Duckworth) and Mr. G. C. Crabbe (representing the amateur gardener section of the Society). A very pleasant evening was spent, and the meeting was acknowledged to be a most agreeable break in the winter programme of the Society. The affairs of the Association were stated to be in a most flourishing condition, and everything in connection with it in as satisfactory a state as could be wished.

— **PRODUCE FROM AFRICA.**—Growers in South Africa are trying to establish a trade in London for their Potatoes and Tomatoes, one farmer offering to furnish 80 to 100 tons of Tomatoes. There appears to be some truth in the statement that "England is the finest market in the world." But why the so-called distress of home growers?

— **RATS AND FRUIT.**—Some time ago a correspondent mentioned in the *Journal* a case of rats taking Gooseberries from the bushes. Where these rodents are numerous near gardens or orchards they do not hesitate to climb walls and trees for the fruit thereon. They appear to have a liking for Pears, and frequently work havoc to the consternation of the gardener or owners.—T.

— **THE WEATHER IN WARWICKSHIRE.**—The current year was ushered in with real wintry weather. On January 1st we registered 9° of frost, and on the 3rd and 5th 20°. A slight fall of snow took place early on Friday morning, 6th inst., and during the afternoon and evening of the same day several heavy snowstorms increased the depth upon the ground to 3 inches.—H. D.

— **AMERICA'S NATIONAL FLOWER.**—The national flower question has been brought before the United States Congress. Congressman Butler, of Iowa, has introduced a resolution that the Pansy be adopted as the national flower, and that the stars on the national flag be arranged in the form of this flower.

— **WEATHER IN MID-WALES.**—We have had some very severe weather here for the last fortnight, commencing on the 23rd of December. We registered from 16° to 25° of frost every night. Once we had 26° and twice 25°. The first week of it was very quiet, no winds whatever; but from the 5th to the 9th the wind was very strong and bitterly cold, and snow fell on the 6th and 7th heavily, and at the time of writing the weather seems to be breaking up.—R. C. WILLIAMS, *Crosswood Park, Aberystwith.*

— **COLOUR AND QUALITY.**—It is singular to see two correspondents (Messrs. H. S. Easty and "A. D.") in your issue of January 5th suggesting, against popular opinion, that yellow is a property in fruit and vegetables. I have for many years been addicted to that taste in all our garden fruits and Potatoes. The former are often not only the most luscious to eat, but are so when cooked or made into jam. In Gooseberries I never found an exception, consequently have a predilection to yellow coloured fruit.—W. T., *Blantyre.*

— **GARDENING APPOINTMENTS.**—Mr. Alexander Penhorwood, for the past eight years gardener to W. H. Budgett, Esq., Stoke House, Bristol, has been appointed gardener to P. D. Pranker, Esq., The Knoll, Sneyd Park, Bristol. Mr. E. Trollope, late of The Firs, Lec, Kent, has been appointed gardener to J. Foster, Esq., Combe Park, Whitechurch, Reading. Mr. Geo. E. Weeks, for the last five years foreman to Mr. G. Inglefield, Tedworth House, Marlborough, has been appointed head gardener to R. D. Cleasby, Esq., Pennoyre, Brecon, South Wales.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The quarterly meeting of this Society was held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday evening last, Mr. W. P. Thomson in the chair. The Society is making good progress, fifty-three members having been elected during the past year. Three members are on the Sick Fund at the present time. One member, who has been ill recently, was allowed 10s. from the Convalescent Fund. The amount of deposit standing to the credit of a non-paying member was granted at the last meeting in accordance with Rule 14, the said member having ceased to pay since 1869, and who has now reached sixty years of age. Messrs. Dixon, Gunner, and Puzey were elected auditors for the past year's accounts. The usual vote of thanks to the Chairman ended the meeting.

— **THE WEATHER DURING DECEMBER AT RIPLEY, YORKS.**—December was ushered in by severe frost, which continued until the 14th; from that date to the 21st we had a spell of very mild weather. On the 22nd frost set in again and continued very severe to the end of the month. On the 29th, 30th, and 31st we registered 24° of frost. The rainfall was very light, the total fall being only 0.67 of an inch, which fell upon eleven days, the greatest daily fall being 0.14 of an inch on the 8th. Mean reading of barometer, 29.94. Mean maximum temperature, 38.5°; mean minimum temperature, 22.6°; mean temperature of month, 30.5°. Fog was prevalent from 19th to 22nd. No snow fell during the month to spread its protecting mantle over the occupants of our borders.—J. TUNNINGTON, *Ripley Castle Gardens.*

— **THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—A general meeting of the members of this Institution will be held at "Simpson's," 101, Strand, on Tuesday, 17th inst., at a quarter to three in the afternoon, to confirm the special resolution of the 20th day of December, 1892, relative to the name of the Institution. The fifty-fourth annual meeting will be held at the same place and on the same date, for the purpose of receiving the report of the Committee and the accounts of the Institution for the present year, electing officers for the ensuing year, and other affairs; and also for the purpose of placing twelve pensioners on the funds. The chair will be taken at three o'clock, and the poll will close at five o'clock. No subscriber can vote whose subscription for 1892 is unpaid on the day of the election.

— **ROYAL PATRONAGE FOR THE GARDENERS' ORPHAN FUND.**—We have pleasure to announce that Her Royal Highness the Princess of Wales has sent a cheque for 10 guineas to this charity. At the last Committee meeting donations to the amount of £66 were announced, including £20 from the Reigate Chrysanthemum Society, a similar amount from Mr. Todd (obtained by the sale of flowers at the Edinburgh Show), £9 from the Rugby Show, £5 from the Carnation and Picotee Society's Show, Edinburgh, with smaller amounts from other collecting boxes. There are forty-nine pensioners on the Fund, and fifteen candidates for eight vacancies. The annual meeting will be held on February 15th. Sir James Whitehead, Bart., M.P., was elected a Vice-President, and Mr. R. Ballantine succeeds the late Mr. C. H. Sharman on the Committee.

— **THE R.H.S. COMMITTEES.**—Amongst new additions to these Committees for the present year (see page 32) are one or two in whom the readers of the *Journal* should feel special interest. Mr. Molyneux will be able on the Floral Committee to give the assistance of his wide knowledge of Chrysanthemums at the autumn meetings, and we hope sometimes for other purposes in the summer. So also will another new member, Mr. C. E. Shea. We are specially pleased also to notice that Mr. A. Young of Abberley Hall, and Mr. W. Iggulden of Marston Gardens, have been added to the Fruit Committee. It is to be deplored that distance prevents these and some other able gardeners, such as Mr. S. T. Wright of Glewston Court, Mr. Divers of Ketton Hall, Mr. McIndoe, and others from only rarely attending. All the same, we are sure they will receive a very hearty welcome when they can do so. Mr. Burrell of Claremont, and Mr. Goldsmith of Leonards Lee, also are new members of the Fruit Committee.—D.

— **WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—A meeting of this Society was held on Thursday last in the Mechanics' Institute, under the presidency of Mr. H. M. Coates. Mr. R. Todd, gardener to Holbrook Gaskell, Esq., Woolton Wood, gave a very interesting address on the Ouvirandra and other curiosities of plant life, including some useful cultural hints. Specimens of the Ouvirandra or Lattice-leaf plant, *Sarracenia Drummondii* and *purpurea*, *Cephalotus follicularis*, *Dionaea* or Venus' Flytrap, and *Nepenthes Hookeri* were on the table, together with the following varieties of Ferns: *Trichomanes radicans* (Killarney Fern) and *T. reniforme*, *Hymenophyllum*, *Rhodopteris peltata* or the Umbrella Fern. Hearty votes of thanks to the Chairman and lecturer were accorded. Mr. D. H. Johns, gardener to W. Revill, Esq., Hill House, Wavertree, brought a fine dish of Conference Tomatoes, for which the Society's certificate of merit was awarded.—R. P. R.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, IN DECEMBER, 1892.**—Mean temperature of month, 34.0°; maximum on the 18th, 34.0°; minimum on the 27th, 10.6°; maximum in the sun on the 19th, 87.6°; minimum on the grass on 27th, 6.5°. Mean temperature of air at 9 A.M., 32.7°; mean temperature of soil 1 foot deep, 37.5°. Nights below 32°; in shade, twenty-two; on grass, twenty-seven. Total duration of sunshine in the month, forty-eight hours, or 21 per cent. of possible duration. We had eleven sunless days. Total rainfall, 0.44 inch. Rain fell on nine days. Average velocity of wind, 8.2 miles per hour; velocity did not exceed 400 miles on any day, and fell short of 100 miles on ten days. Approximate averages for December.—Mean temperature, 37.1; sunshine, thirty-two hours; rainfall, 1.97 inch. Very dry and cold, but sunny and calm. A spell of frost at the beginning of the month, and another and sharper one at the end, but with practically no snow. The rainfall was smaller than in any corresponding month during the last sixteen years, but we have had three colder ones.—J. MALLENDER.

— **MASTERS AND WORKMEN.**—On Wednesday the 4th inst., the employés of Messrs. Thos. Rivers & Son were entertained to supper in one of the large houses, which was decorated for the occasion. About ninety-six men sat down to a substantial meal, the catering being in the hands of Mr. and Mrs. Camp. Mr. T. F. Rivers, in response to the toast of Messrs. Rivers & Son, said he was most happy to see all his men around him, and that it was owing to them and to their careful attention to their duties that the name of Rivers was so well known, not only in England, but in every quarter of the globe. He trusted that the friendship which existed would continue for years to come.

growers of the north are cordially supporting the Society, and it is hoped also that the southern growers will be able to come in full strength. Tamworth is easily reached, being about half way between Birmingham and Derby.

#### KEEPING GRAPES.

THE plan I adopt for keeping late Grapes is very simple, and I find it answers well, as I always keep them fresh and plump in the berry till the early varieties are ready for cutting, which, as a rule, are ready about the middle of May.

FIG. 5.—A PORTION OF THE GRAPE ROOM AT FLOORS CASTLE.

— **THE MIDLAND COUNTIES PANSY SOCIETY.**—The schedule of prizes for the third annual Exhibition of this Society has been issued, and we note that the Exhibition for 1893 is to be held at Tamworth, Mr. W. Dean still remaining the Hon. Secretary. It is the most liberal schedule of prizes ever offered for Pansies and Violas alone, the large sum of £64 being devoted to prizes, chiefly in cash, but some medals are offered. In addition there are special prizes for lady exhibitors for a wreath, cross, basket, or spray of Violas or Pansies, handsome prizes of jewellery to the value of £14 being offered for these separate classes. Whilst several of the classes are for the growers in the midland counties only, a goodly number are open to the United Kingdom; and it is hoped that something in the character of a national meeting of growers will result, and that a very large display of blooms will be secured. The

It will be seen by the photograph that the bottles are fixed in shelves made purposely for keeping Grapes. The bottles are filled with clean water, with two or three pieces of charcoal in them to act as a purifier. Many recommend sugar, saying it adds flavour to the Grapes; but the point I aim at is to try and get the sugar in them before they are cut.

I always start my latest vinery on March 1st, and that gives me a good chance of getting the Grapes well coloured and ripe by the end of September. Grapes that are not finished by that time stand a poor chance of ripening properly, and I find that those well ripened keep much the best.

Thinning is another chief point in keeping Grapes. I always thin my Grapes well, especially those that are for keeping, leaving no inside

berries, as I find the thinner they are, in reason, the better they keep. I always like to see the berries stand clear of each other, and if properly thinned, Lady Downe's will, as they are short in the stalk and will bear their own weight.

When cutting Grapes for keeping I always cut plenty of wood with them, say a foot to 18 inches beyond each bunch, and as much as possible from the spur to the bunch, leaving two or three buds to prune to. I think this adds greatly to the keeping of the Grapes. With some bunches it is impossible to get the wood long enough to go into the bottle—that is from the spur; in that case I find they keep just as well by inserting the wood from the bunch or the lateral end in the water.

I make a rule of examining my Grapes once a week, filling all the bottles that require water, and cutting out all bad berries. The Grape room is kept dark and cold, never using artificial heat only during damp or very frosty weather. By following that plan I have kept Lady Downe's Grapes till June 10th fresh and plump in the berry.—*C. STREET, Floors Castle Gardens.*

[The illustration (fig. 5) represents but a small portion of the end of the Grape room. The photograph was out of proportion, and if the whole of it had been engraved, it would necessarily have been so reduced as to spoil the effect. The woodcut, however, portrays Mr. Street's method of keeping Grapes. He sent us a model bunch with fine berries admirably thinned.]

## THE ROYAL HORTICULTURAL SOCIETY.

### COMMITTEES.

THE arrangements of the Royal Horticultural Society for 1893 have just been issued, and, apart from the customary periodical meetings, a special four-days Exhibition will be held at the Agricultural Hall, Islington (see page 28), in addition to the usual Temple Gardens Show, which takes place on May 25th and 26th. An Exhibition will also be held at the Chiswick Gardens on July 11th, and the respective Shows of the National Auricula, Carnation, and Rose Societies take place as usual at the Drill Hall, Westminster. A new feature will be the Exhibition of the recently formed London Pansy Society alluded to on page 29, which will be held on July 6th. We publish the names and addresses of the members of the various Committees for the current year.

### SCIENTIFIC COMMITTEE.

*Chairman.*—Sir Joseph Dalton Hooker, K.C.S.I., M.D., C.B., F.R.S., The Camp, Sunningdale.

*Vice-Chairmen.*—Dyer, W. T. Thiselton, C.M.G., F.R.S., Royal Gardens, Kew; Foster, Professor M., Sec. R.S., Great Shelford, Cambridge; Masters, Maxwell T., M.D., F.R.S., V.P.L.S., Mount Avenue, Ealing, W.

*Hon. Secretary.*—Rev. Prof. G. Henslow, M.A., F.L.S., F.G.S., Drayton House, Ealing, W.

Baker, J. G., F.R.S., Royal Gardens, Kew.

Balfour, Prof. I. B., F.R.S., Botanic Gardens, Edinburgh.

Blandford, W. H. F., M.A., F.E.S., 48, Wimpole Street, W.

Bonavia, Dr. E., 5, Harrington Mansions, South Kensington.

Burbridge, F. W., F.L.S., Trinity College Gardens, Dublin

Church, Professor A. H., F.R.S., Shelsley Gardens, Kew.

Clarke, Colonel R. Trevor, Welton Place, Daventry.

Darwin, Francis, F.R.S., Wychfield, Huntingdon Road, Cambridge.

Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire.

Elwes, H. J., F.L.S., F.Z.S., Colesborne, Andoversford, Gloucestershire.

Engleheart, Rev. G. H., Appleshaw, Andover.

Farmer, Prof. J. Bretland, M.A., Royal College of Science, South Kensington, S.W.

Frankland, E., F.R.S., The Yews, Reigate Hill, Reigate.

Gilbert, J. H., Ph.D., F.R.S., Harpenden, Herts.

Godman, F. DuCane, F.R.S., 10, Chandos Street, Cavendish Square, W.

Green, Professor J. R., M.A., 17, Bloomsbury Square, W.C.

Lindsay, R., Botanic Gardens, Edinburgh.

Llewelyn, Sir J. T. D., Bart., F.L.S., Penllergare, Swansea.

Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.

McLachlan, R., F.R.S., Westview, Clarendon Road, Lewisham, S.E.

Michael, Albert D., F.L.S., Cadogan Mansions, Sloane Square, S.W.

Morris, D., M.A., F.L.S., 11, Kew Gardens Road, Kew.

Müller, Hugo, Ph.D., F.R.S., 13, Park Square East, Regent's Park, N.W.

Oliver, F. W., D.Sc., F.L.S., 10, Kew Gardens Road, Kew.

Pascoe, F. P., F.L.S., 1, Burlington Road, Westbourne Park, W.

Plowright, C. B., F.L.S., 7, King Street, King's Lynn.

Russell, Dr. W. J., F.R.S., 34, Upper Hamilton Terrace, N.W.

Salvin, Osbert, F.R.S., Hawksfold, Fernhurst, Haslemere.

Scott, D. H., M.A., Ph.D., F.L.S., The Old Palace, Richmond, S.W.

Stewart, Prof. C., Royal College of Surgeons, Lincoln's Inn Fields, W.C.

Symons, G. J., F.R.S., 62, Camden Square, N.W.

Veitch, H. J., F.L.S., Royal Exotic Nursery, King's Road, Chelsea, S.W.

Ward, Professor Marshall, F.R.S., The Laurels, Englefield Green, Staines.

Wilson, Geo. F., F.R.S., Heatherbank, Weybridge Heath.

### FRUIT AND VEGETABLE COMMITTEE.

*Chairman.*—Crowley, Philip, F.L.S., Waddon House, Croydon.

*Vice-Chairmen.*—Bunyard, George, The Nurseries, Maidstone; Lee, John, 78, Warwick Gardens, Kensington; Rivers, T. Francis, Sawbridge-worth.

*Secretary.*—Archibald F. Barron, Royal Horticultural Society, Chiswick, W.

Balderson, H., Corner Hall, Hemel Hempstead.

Bates, W., Poulett Lodge Gardens, Twickenham.

Bennett, W., Rangemore Park Gardens, Burton-on-Trent.

Burrell, E., Claremont Gardens, Esher.

Cheal, Joseph, Crawley, Sussex.

Coleman, W., Eastnor Castle Gardens, Ledbury.

Cummins, G. W., The Grange Gardens, Wallington.

Dean, A., Bedford, Feltham.

Divers, W. H., Ketton Hall Gardens, Stamford.

Dunn, Malcolm, The Palace Gardens, Dalkeith, N.B.

Goldsmith, Geo., Leonardslee Gardens, Horsham.

Hogg, Dr., LL.D., F.L.S., 99, St. George's Road, Pimlico.

Hudson, J., Gunnersbury House, Acton.

Iggulden, W., Marston Gardens, Frome.

Laing, J., jun., Forest Hill, S.E.

Lane, Fred. Q., Berkhamsted.

McIndoe, James, Hutton Hall Gardens, Guisborough.

Miles, G. T., Wycomb Abbey, High Wycomb.

Norman, G., Hatfield House Gardens, Hatfield.

Pearson, A. H., The Nurseries, Chilwell, Notts.

Reynolds, G., The Gardens, Gunnersbury Park, Acton.

Ross, Charles, The Gardens, Welford Park, Newbury.

Sage, G. H., Ham House Gardens, Richmond, S.W.

Saltmarsh, T. J., The Nurseries, Chelmsford.

Smith, James, The Gardens, Mentmore, Leighton Buzzard.

Sutton, A. W., F.L.S., Reading.

Taber, G., Rivenhall, Witham, Essex.

Veitch, A., King's Road, Chelsea.

Veitch, P. C. M., The Royal Nurseries, Exeter.

Warren, W., Worton Gardens, Isleworth.

Weir, Harrison, Sevenoaks.

Willard, Jesse, Holly Lodge Gardens, Highgate, N.

Wright, John, 171, Fleet Street.

Wright, S. T., Glewston Court Gardens, Hereford.

Wythes, G., Syon House Gardens, Brentford.

Young, A., Abberley Hall Gardens, Stourport.

### FLORAL COMMITTEE.

*Chairman.*—Marshall, William, Auchinraith, Bexley.

*Vice-Chairmen.*—D'Ombraim, Rev. H. H., Westwell Vicarage, Ashford, Kent; Fraser, John, Lea Bridge Road, Leytonstone, E.; Paul, George, The Old Nurseries, Cheshunt.

*Secretary.*—Archibald F. Barron, Royal Horticultural Society, Chiswick, W.

Bain, W., The Gardens, Burford Lodge, Dorking.

Baines, Thomas, Fern Cottage, Palmer's Green, N.

Barr, P., 12, King Street, Covent Garden, W.C.

Bause, F., Portland Road, South Norwood, S.E.

Cannell, H., Swanley, Kent.

Cant, F., Braiswick, Colchester.

Dean, R., Ranelagh Road, Ealing, W.

Druery, C. T., F.L.S., 25, Windsor Road, Forest Gate.

Fitt, J. H., The Frythe Gardens, Welwyn.

Furze, W., Roselands, Broom Road, Teddington.

Girdlestone, T. W., Sunningdale, Berks.

Godfrey, Thos., Hillingdon, Uxbridge.

Gordon, G., 1, Style Villas, Gunnersbury.

Herbst, H., Kew Road, Richmond, Surrey.

Ingram, W., Belvoir Castle Gardens, Grantham.

Jeffries, C., Boston House Gardens, Brentford.

Jennings, J., Ascott Gardens, Leighton Buzzard.

Laing, J., Forest Hill, S.E.

Webster, A. D., F.B.S.E., Holydale, Keston, Kent.

White, Miss, Alexandra College, Dublin.

## PROGRESS IN PRIMULAS.

It would be difficult to write anything fresh about many flowers were they standing still, for references have been made to them by able pens "many a time and oft;" but when the march of improvement still goes on it is not without interest to come back to them occasionally, if only for the sake of reporting progress. What of originality could be introduced, I wonder, into a dissertation in praise of Primulas were this consideration disregarded? Their beauty has been described, their points of merit enlarged upon, their usefulness proclaimed in one unending chorus, idle, therefore, the attempt to say aught that is

fresh about them without taking account of the past and present work of the hybridiser. When, however, this field is entered upon abundant material is found for comment. With the Primula there is no marking time, for even when after a long course of development the raw recruit has been turned into the smart cavalier, much polish remains to be put on.

There is one fact which stands out as the most remarkable of all in connection with the marvellous improvement effected in Chinese Primulas, and it is their production from one species. We often talk loosely of hybridisation, but, properly speaking, our Primulas are not hybrids at all; they are cross-breeds. Think what this means. In crossing distinct species we pave the way for variations, breaking up, as it were, certain lines of form and colouring which Nature has laid down, and consequently leaving no room for surprise if the disturbance finds expression in other ways than those aimed at when the hybridisation was effected. But variation by change of environment, by selection, and subsequently by cross-breeding, is a different thing, and the results are often such as astonish even the most experienced observer. Here Nature has not, so to speak, been thrown off her balance by the abrupt intermingling of different bloods. The capacity for improvement was inherent, not imparted, and what has been done is in no sense a creation, but simply a development of latent resources.

The interest of this reflection deepens when an opportunity is presented of seeing the best examples of the developing process side by side with their modest original, and it is only natural that this should add emphasis to any conception that may have been formed by reading alone. In the case of many plants the lesson is denied, for the (to us) primordial form has disappeared; but in that of the Primula it may be learned by anyone who visits the nurseries of Messrs. Sutton & Sons at Reading, where such great work has been done in the improvement of this valuable flower. In the same house which shelters some of the most remarkable examples of their success, plants of the original *Primula sinensis* are blooming, and a striking contrast is presented between it and such magnificent varieties as Pearl, Purity, and Ruby King. For actual quality of flower it may be measured with, let us say, *P. obconica*, although quite distinct from that useful sort, and this will serve to indicate the great disparity between it and its brilliant offspring. It is not suggested that *P. sinensis* is devoid of beauty, very far from that. Its flowers are five-petalled, almost star-shaped, and of a delicate lilac-blush tint. The habit is neatness itself, and altogether the plant is so pleasing that if met with for the first time it would certainly invite comment and attention. But as it is, it is impossible to dissociate it from the varieties which have sprung from it, and instead of studying its points of merit the natural impulse is to seek out resemblances to the improved forms. In this connection it is interesting to note the variations in both foliage and flowers; even in a small batch of plants there are distinct shades of colour, although no marked divergences, and in the leaves there are clear indications of variation from the palmate to the fern-like form. So far as hybridisation is concerned it is curious to note that hitherto *P. sinensis* has refused to mate with any other species.

A new interest is added to the inspection of the choice varieties raised at Reading after thus making acquaintance with the parent form. Cross-breeding still goes actively on, and the results are, in many cases, as unexpected as they are interesting. The erection of three splendid new houses has permitted of the further enlargement of the previously extensive collection, this step having been rendered necessary by the increasing demand for seed. The fresh structures are models of design, material, and workmanship. One of them is devoted to a trial of all the varieties offered, together with many others, so that not only are errors in the supply of seed guarded against, but every claimant for attention is tested on equal terms with the standard sorts. From a cultural point of view the collection is almost beyond praise. The thousands of plants are full of health and vigour, and although there are natural variations in habit and size, the general characteristics are compactness of growth, broad stout leafage, bold trusses borne well up above the foliage like the flowers of a good Begonia, large, substantial, well-formed flowers, and clear, decided colours. It is impossible to conceive a fastidiousness so great as to be unable to find abundant food for pleasure and satisfaction in a collection of such extent, diversity, and beauty.

The single palmate-leaved varieties number some of the loveliest Primulas in cultivation. Pearl is an old favourite, having been out since 1879; but it is still one of the best, its fine truss and large, pure white, beautifully fringed flowers awakening deep admiration. Ruby King, another of the firm's early triumphs, indeed the one which first brought their work amongst Primulas into prominence, is also in the front rank yet; and taking into consideration its free blooming and rich distinct colour, it may be expected to remain there for many years to come. It was certificated in January, 1879. Giant Crimson and Giant White are fitting illustrations of the advance on the old varieties rubra and alba, while Brilliant Rose and Giant Reading Pink are perfect examples of their own shade of colour. The latter is the result of years of work. It is a magnificent variety, having a noble truss and fringed flowers of great size. Reading Blue is not only rich in colour, but has the prevailing qualities of its associates. There are half a dozen Fern-leaved varieties of conspicuous excellence. First may be noted Purity, the Pearl of the section, with its large, pure white flowers and fine truss. The chaste blooms of this beautiful Primula are admirably shown up by the dark foliage. Snowdrift is particularly valuable on account of its rapid growth, earliness in blooming, and profusion. It is flowered in

three months from the time of sowing, covers itself with blossom, and remains in beauty for a very long period. Gipsy Queen and Rosy Queen are a delightful pair, the former being conspicuous from its very dark foliage, and the latter for its very dwarf and compact habit, but both have charming flowers. Sutton's Blue is of vigorous growth, has a fine truss, and possesses a lovely shade of colour.

The doubles exhibit the same general qualities as the singles. They have been improved up to a point beyond which it is very difficult to get. All the varieties are remarkable for their huge trusses of bloom and fine colours. Double Rose is particularly beautiful, its rosy blush or Miss Joliffe Carnation hue making it a universal favourite. Double Scarlet and Double Crimson are both exceedingly rich, and they have large, full flowers with which to display their brilliant colours to the best advantage. Double White and Double White Fern-leaved are both splendid varieties, having large, well-developed individual blossoms united in a handsome truss. Gem is also a charming Primula, its foliage alone rendering it attractive. In habit it is perfect, and the rosy flowers are borne lavishly.

Besides those grown under name there are some beautiful crosses, the character of which cannot be satisfactorily fixed. These are sold as special mixed hybrids, and considering their distinct and meritorious character they ought to prove an investment of no small interest. In thus referring to the mixtures it may be well to note that the seed sold as such is in reality a mixture of the different varieties grown, not of the red and white alone. There is also a distinct moss-curved section growing up which in course of time is sure to be widely sought after. The plants have curled and cut moss or parsley-like leaves.

An opportunity should be sought of making a personal inspection of what Messrs. Sutton have done and are still doing with Primulas at Reading. As the large collection is grown with a view to providing an effective display over a long period it is impossible to catch its full beauty at any one particular time, but at no period during the season can it be seen without a magnificent spectacle being admired. Cyclamens and Cinerarias (to which reference may be made on a future occasion) supplement it, and the three classes vie with each other in beauty and quality.—W. P. W.

## DISCUSSION ON POTATOES.

### QUALITY *versus* SHALLOW-EYED TUBERS.

I HAVE in my day devoted considerable time in raising and cultivating seedling Potatoes. I have always aimed at shallow-eyed tubers, but although I have several of them for years untouched with disease I never find a shallow-eyed Potato up to my standard of quality. The quality of Potato I prefer is a tuber that boils or cooks soft yet firm, and of a slightly sweet taste, and if the flesh is yellowish it is sure to be a Potato for the million. Give me quality first, then beauty, or in other words, I prefer Potatoes serviceable for the dinner table rather than the show board.—W. T., *Blantyre*.

### A TREAT.

DISCUSSING the merits of Potatoes with an extensive grower of them, the question arose as to whether the good old sorts of long ago had really been superseded in quality. "You don't grow the old favourites now, I suppose?" quietly remarked my friend; "I will send you a few as a treat." What will the modern men, the men up to date in Potato matters, think of his taste when I name the varieties—Dunbar Regent, Lapstone, Fortyfold? and what will they think of my taste also when I say the Potatoes were a treat indeed, and distinctly superior in texture and flavour to at least fifty more or less new varieties that were prepared by the same cook? I should like to know of three others to beat them.—PAT MURPHY.

### YELLOW-FLESHED POTATOES.

I HAVE raised seedling Potatoes for more than half a century, and always found those having yellow-coloured flesh or skin the finest flavoured, unless the yellow tuber was a sport, in which case the flavour was inferior; but I can no more explain the reason of this than that yellow is otherwise an indication of quality and fine flavour. Like Mr. Robt. Fenn, I strive for quality first, next for quantity, and lastly for appearance, then I make a strong effort to combine the three. I am sure I endorse the opinion of thoughtful persons in saying that there is too much pandering to the taste for showiness apart from edible and nutritive properties in Potatoes.—W. T., *Blantyre*.

### THE BEST VARIETIES.

I AGREE with Mr. Easty, page 5, as to the advisability of having a discussion on Potatoes as well as on Apples. The great thing in invoking discussion is to secure something like sequence or continuity, and to avoid rambling. We may discuss the merits of early and of late Potatoes, especially of varieties, also of frame and pot culture under glass; then of best forms of planting and culture for early varieties and for late varieties, suitable manures, best varieties for exhibition, &c., and in that way cover very wide ground. Suppose we start by asking what are the best half dozen of first early varieties? Of course these will be all white-skinned and largely kidney, although some may be of the round section. What difference of opinion will the naming of but half a dozen first earlies evoke. Very much will depend upon knowledge. Amongst the best, Laxton's Early Short Top, mentioned by Mr. Easty, is one, a first-class variety for frame and pot culture or for close planting on

warm borders. It is an oval kidney shape, walnut-leaf top, a remarkable cropper, and excellent quality. This has for two seasons at Chiswick proved to be one of the very best earlies. Albert Victor (Sharpe) everyone now knows of, and is one of the very best. Then King of the Earlies (Ridgewell) is, as was shown at Chiswick, a first-rate Ashleaf Kidney. It is a seedling variety, heavy cropper, and so far as has been seen of it, one of the best of the Ashleaf section. Guardian (Dean) is an early kidney not much known, but Mr. Lockie of Windsor can speak of it in very high terms as a first-class early kidney for warm soils. Ringleader (Sutton) is one of those good flavoured nutty flesh sorts that are so valuable for early work. It is a heavy cropper, and very early. Then Duke of Albany, otherwise White Beauty of Hebron, is a capital first early for borders or for small gardens and allotments. I prefer this Potato to Puritan, and think that no American kind excels it.

Then, turning to second earlies, there are Suttons' Seedling, and also their Early Regent, both delicious varieties and capital croppers, flattish round in shape, and very good form. Snowdrop is a kidney of such good reputation that it only needs mention. Snowball (Dean) is a short-topped handsome early round, that is specially good for garden culture. Fidler's Prolific and Snow Queen are further two capital rounds in this section, both fine croppers and of great excellence. A midseason selection must include such fine varieties as the red Reading Russet, the purple The Dean, the white Schoolmaster, Covent Garden Perfection, Windsor Castle, and The Daniels, a very fine white kidney and a heavy cropper.

Then, for a later or main crop selection there is our old friend Magnum Bonum, Suttons' Satisfaction (a very fine flattish round), The Bruce, Reading Giant, Stourbridge Glory, and Chancellor. I think it will be found very difficult to beat this selection.

It will be seen that I have gone far beyond my original suggestion, and have mentioned twenty-four varieties, covering the entire year. There can be no doubt whatever but that to those engaged in Potato culture the subject is of extreme interest. In earlier days when I was engaged in raising new varieties and in growing them I naturally had my favourites. Now I have none whatever, and, therefore, can recommend any most impartially. I do, therefore, think that the twenty-four varieties named can hardly be excelled for covering a long season, for general goodness of quality, or for abundant cropping.

Were I about to select the best twenty-four for exhibition I should make considerable changes, as for instance, the first earlies would hardly be included, as exhibitions of Potatoes are rarely held early in the season; whilst in the autumn many of the later varieties give much finer and handsome tubers. Taking the four sections of white round and white kidney, coloured round and coloured kidney in this order, I should give of the former six—viz., London Hero, Windsor Castle, Schoolmaster, Satisfaction, Prime Minister, and Snow Queen. Of white kidneys, eight—viz., Snowdrop, The Canon, Reading Giant, Supreme, Chancellor, Duke of Albany, Magnum Bonum, and Cosmopolitan. Of coloured rounds six—Reading Russet, King of the Russets, The Dean, Vicar of Laleham, Lord Tennyson, and Radstock Beauty; and of coloured kidneys four—Beauty of Hebron, Reading Ruby, Edgcote Purple, and Mottled Beauty, a purple flaked Lapstone.

I have before me a list of some sixty varieties all recommended for exhibition. Whilst it is very obvious that such a list would only better anyone wishing to grow a couple of dozen sorts, it is equally certain that at least one-half are now seldom seen at exhibitions. Very many of the old show sorts are now regarded as comparatively small, or else of indifferent quality. So far as is possible, all these I have excluded from the latter list, even such a still highly favoured show variety as the old International, being excluded. Its place is now most worthily taken by the Canon. It is a matter of much importance that distinctness should be found in collections of Potatoes. Too much alike is often the complaint, and it was a marked cause for complaint at the great Earl's Court Potato Show. Whilst of no special importance so far as mere eating varieties are concerned, it is of material consequence when Potatoes are exhibited in collections, and the Magnum Bonum type of kidney specially give trouble, and so also do the long flattish rounds, for these are so alike that some half dozen that have diverse names, but could all have been picked from the same sort, are often seen in the same collection. Coloured varieties are fewer, and are also more distinct; indeed there is hardly two of these that will be confounded one with another, except it be, perhaps, Beauty of Hebron and White Elephant, and both these should now be tolerated in the same collection. Those who draw up schedules should insist upon absolute distinctness of character in the tubers of each variety shown being beyond doubt, and that may easily be secured, especially in the case of twelve varieties. Judges at small shows should never allow any one sort to be shown as both kidney and round, and in all cases should make distinctness of the first importance.—A. D.

### SOIL AND VARIETIES.

THE suggestion of Mr. Easty, page 5, is quite opportune. This vegetable is undoubtedly the most important of any. In all gardens, those of the rich especially, flavour in a Potato ought to be the first consideration; but I am afraid it is not so, there is too much hankering after appearance. It is surprising how the quality of varieties change in various soils, what will be a success in one garden will be quite a failure in another. Heavy soils are the worst to deal with for Potato culture. Take, for instance, the variety Vicar of Laleham; in light soil the tubers are of good quality, whereas in that of a heavy retentive

character the tubers boil like soap. If those who take part in the discussion would, in naming favourite varieties, state the kind of soil in which they are grown, such information would be really valuable. In common with many others I used to pin my faith on Myatt's Prolific for the earliest supply in strong soil, but it is superseded by Ringleader (Sutton's) both in earliness and flavour. It is good when fresh dug, and retains its quality for months. Sutton's Seedling is a capital second early, although in some seasons it is rather liable to disease. Windsor Castle provides one of the finest late Potatoes we have. Lady Truscott I look upon as the best of the midseason kinds. Where exhibiting is not practised half a dozen varieties are quite sufficient to supply the wants of a good sized family. The soil here is heavy, cold, and retentive, and not calculated to bring out the highest qualities of any Potatoes.—E. MOLYNEUX, *Swanmore Park*.

#### THE COST OF MANURING FRUIT TREES.

As "W. P. W." seems bent on misunderstanding my queries I do not desire to occupy your space with further useless discussion. I must, however, conclude by pointing out, in justice to myself, that I never asked nor wanted any information respecting my own trees. On the contrary, all I wished was to ascertain, if possible, the total cost of applying certain artificial manures recommended by "W. P. W." to particular trees whose fruit he had held up to the admiration of your readers. This apparently simple inquiry has caused him to fly off at a tangent, complaining, amongst other things, of the vagueness of my question, while overlooking the fact that it was a verbatim quotation from his original letter! Your correspondent appears unable to supply the only information I sought, or would be of any practical value.—B. D. K.

[Our correspondent's reply to the above note is as follows:—"My simple parallel about the suit of clothes, it seems, has failed to enable 'B. D. K.' to comprehend the point of the matter. I will give him the A B C of it. If fertilisers are applied at the rate of 4 ozs. to the square yard, a tree covering 10 square yards will want 2½ lbs.; but one covering 5 square yards will only require 1¼ lb. The quantities being different the expense will also vary; consequently when he asks the cost of manuring trees, the only answer is that it depends upon their size. The quantities of the manures named would enable those readers who wished to use them to easily determine the cost per tree to themselves. I know to a farthing how much it costs to manure trees when I do them myself. I hope 'B. D. K.' now understands. The matter is worked out very much on the same principle as that two and two make four. Whether the trees referred to are your correspondent's, mine, or someone else's does not alter the rules of arithmetic.—W. P. W."]

#### FORMATION OF SCHEDULES.

I AM very pleased to see that this matter is being taken up and ventilated in the *Journal of Horticulture*. No doubt that within the next few weeks schedules representing most of the horticultural exhibitions of the kingdom will have to be considered and revised. It is very necessary that committees entrusted with this important work should not only carefully consider each class upon its merits, but every line and every word should be well thought out and carefully defined in order to prevent as far as possible any disputes and misunderstandings which may arise between exhibitors and officials.

Exhibitors, too, will do well to carefully peruse all the matter contained in the schedule. Looking through the classes and noting the amount of prize money is not sufficient; but the rules and regulations under which such prizes are awarded should be well considered. Anyone officially connected with horticultural societies knows very well what an amount of correspondence may be spared them if only a little more care and attention were bestowed upon this matter by exhibitors.

The mixing of advertisements between the leaves of the schedule is a custom that should not be sanctioned under any circumstances whatever. I consider that every word of matter belonging to the Society is of too great importance to allow anything being put in that is at all likely to draw attention from it. No doubt advertising in schedules is a source of income which many societies will not readily abandon; but if it is necessary to have advertisements, then I say by all means let them be kept quite separate and distinct from schedule matter, and divide them by a blank page. Personally I prefer to see a well printed and neatly bound schedule, containing no extraneous matter whatever, rather than one so voluminous that requires so much perusal to find what you are looking for.—JAMES HICKS.

#### TINNEA ÆTHIOPICA.

WITH this note I am sending you a flowering spray of a most beautiful stove plant, and one moreover that appears to be exceedingly scarce. As a rule *Tinnea æthiopica* (fig. 6) commences to flower early in the year, and by the beginning of February the plants are at their best. This year, however, my plants are flowering much earlier than usual, which, in my opinion, enhances their value considerably.

Not only is the plant elegant in habit, and the flowers richly and

distinctly coloured, but they also possess a delicious fragrance very strongly suggestive of Violets, so that a few specimens in bloom will agreeably perfume a moderately large house. When, in addition to these qualities, the season of its flowering is considered, further recommendation is needless. The corolla is two lipped, the lower lip being of a fine maroon colour, and the upper one more of a rich crimson hue. The calyx is large, slightly inflated, and pale green. The flowers are freely produced in axillary clusters at the upper portion of the shoots.

The culture of the plant is easy. A stove temperature is required, and this may debar many amateurs from growing it. A light, rich compost of loam, leaf soil and sand, suits the plant well; and the pots

FIG. 6.—*TINNEA ÆTHIOPICA*.

should be carefully drained. Cuttings of the young shoots strike readily under a bellglass in a little bottom heat.—F. M. B.

#### DISCUSSION ON APPLES.

##### D'ARCY SPICE APPLE.

I HAVE been much interested in the notes on Apples which have appeared in the *Journal*, and I have patiently waited for the above variety to be mentioned. I do not think this Apple is well known, but those who once try will never fail to grow it. It is by no means beautiful in appearance (I have had very ugly fruit on two trees I had in Essex, but here in Suffolk on a clay soil it is not so bad), being usually of a russety green colour, but in hot summers it carries a dull red flush on the sunny side. The most important recommendation consists in the delicious taste the fruit has in the months of February and March, for no Ribston Pippin is better, and it is the best follower to that old favourite. It is a very fair cropper, and the tree a good grower, being clean and healthy. It commands the highest price of all in districts where it is known, but I found it useless to send to London, where I suppose it was unknown, and was not sufficiently highly coloured for that market. It is not so hard in texture as the Ribston Pippin, and therefore will find favour among people who cannot digest hard Apples.

##### FEARN'S PIPPIN.

This Apple is called hercabouts (Suffolk) "None so Pretty," and I think it fairly comes up to this name, being very pretty indeed, but the taste does not come up to appearance. It is, however, very saleable, and, being a fair cropper, it is profitable to grow for market. I find it is not such a clean grower as might be desired on my heavy soil, but doubtless

it is better elsewhere, for I believe it is very largely grown about London. And now, Mr. Editor, as "Apple notes" have been so much appreciated, why not Pear notes?—H. S. EASTY.

#### APPLES ON THE PARADISE STOCK.

FROM the note by Mr. Turton (page 14) regarding the variety Northern Spy, I learn that the tree in question is growing on the Paradise stock, and in a stiff cold clay. Is it not generally understood that soil of this character is unsuitable to the growth of this stock? At least this has been my impression. Many persons assert that no other stock will give the same early results of fruit bearing as the Paradise, but that is a mistake, as I can prove. Nothing could be better than the crops of fruit obtained here the second and even the first year of planting bushes growing on seedling Apple stocks. With such results I for one do not think Paradise stocks are a gain at all, but the reverse; the trees on the Apple stock cover much more space in a shorter time than those worked on the much-lauded Paradise. Perhaps this experience does not coincide with that of many others, but it is an undoubted fact.—A YORKSHIREMAN.

#### APPLE HISTORY.

THE Apple as a fruit and the Potato as a vegetable give precedence with me over all other their food congeners whatsoever, provided they are of a medium size. The papers on the Apple that have followed each other in these pages have been very interesting reading, and I hope what I am now about to throw off may prove interesting also.

It must be over seventy years ago that the Ladies Mary and Elizabeth Broadhead resided in the Deputy Ranger's Lodge, Holly Grove, Windsor Great Park. My wife's father, Thomas Temple, worked in the garden, and he remained there as gardener under successive Deputy Rangers till General Seymour became Marquis of Hertford. It is necessary that I should mention this, as it becomes dovetailed for my story.

It so happened that the above-mentioned ladies were returning from a journey and had to pass through Woodstock, where they stayed a night at the Bear Inn. One Kempster, a shoemaker, lived at Old Woodstock. He was the raiser of the famous Apple since named the Blenheim Orange Pippin, and he must have been then in about the beginning of his fame as the raiser of so famous an Apple. Let us surmise so, judging as I do by the appearance of the tree when I first saw it in 1847. The last time I did so—long, long after that—I was accompanied by the Rev. William Clarke, the then Curate of Wootton, a brother of our R.H.S. Col. Clarke. Old Woodstock was then a hamlet of Wootton. The Rev. W. Clarke was, like his brother, very fond of horticulture. I remember he took a drawing of the old tree, and I think he sent it to the *Illustrated London News*. A basket maker, Grimmet by name, succeeded to Kempster the shoemaker. Grimmet cared nothing about trees, so not long after the above I made another visit to him for the purpose of purchasing the old tree stock if I could, and to work or get it made into some suitable memento. Alas! he had cut it down and burnt it as being "no good on," and it was in the way of younger Apple trees. I had, fortunately, previously secured some decrepit scions from the old tree and grafted them on to the only stocks that offered, miserable cripples, which grew in a garden handy. Cottages and gasometers now occupy the garden site of the original Kempster Apple. Thus fame passeth away! I have been thus minute in describing the site of the old tree, &c., because there may be someone living in the neighbourhood or at the Woodstocks who can remember between forty or fifty years ago, and to whom this anecdote may hark them back to the Kempster Apple tree.

I will return to the sisters Broadhead, who were so charmed by the appearance of the fruit placed by "mine host" on the table for dessert, that they took an Apple home with them for the purpose of raising some young trees in memoriam. The pips were sown by the sisters in two flower pots. Two germinated, and when grown sufficiently large my wife's father was requested to plant them, one on each side of the broad kitchen garden walk at Holly Grove, where they are now in all probability. At any rate, my father-in-law brought me some scions from each of the trees to Woodstock Rectory; I grafted them, and brought the resulting trees bodily away with me to Sulhamstead, Berks, only two hours' journey from where their relatives were raised. You have seen them here, but then time would not have allowed me to go into particulars as above. I will further beg to submit an opinion that in all probability the Broadhead seedlings from the Blenheim Orange were the first of the ilk ever raised. At any rate, the first raised that can be directly traced, and where in living arboriculture can be traced trees other than mine directly handed down by grafts from the old original?

Now, having given you the details so far, I cannot but feel, as you are the leading fruitists of the day, that you will be interested in the Apples I send, both ocularly and epicureally.

No. 1 is the produce, in a direct descent by graft, from the original tree; No. 2 is Lady Mary Broadhead Seedling; No. 3 Lady Elizabeth Broadhead. Here we gain a departure from the first original feature, also a sharper flavour and a firmer and a longer keeping variety. No. 4 is my Apple that I have named Pay-the-rent. I found an old tree of it here for which I could never find a recognised name. I am propagating it largely for myself, as I consider it to be an excellent household Apple. Pray do not tell me it "lacks size and colour"—these bugbears are leading us like will-o'-the-wisps.—ROBT. FENN.

[We will not say that Pay-the-rent lacks size. It is large enough, very symmetrical, round, green, and somewhat russety, and the fruits

being uniform in size form an excellent sample. This is, no doubt, a serviceable culinary Apple, and as the tree appears as free and healthy in growth as Golden Noble, and about as productive as Dumelow's Seedling, we suspect our correspondent has acted wisely in planting it largely. Lady Mary is a very fine form of the Blenheim, the fruits larger than those from grafts of the original tree. Lady Elizabeth is more conical, smaller—dare we say rather too small—and brisker than either of the others. We will have Pay-the-rent cooked as requested by its discoverer.]

#### NATIONAL CHRYSANTHEMUM SOCIETY.

IF Mr. Dean regards the Floral Committee of the National Chrysanthemum Society as a kingdom of his own creation this may account for his taking any suggestion made as a personal attack, for he is a poor monarch who will not defend his own kingdom.

Mr. Dean says country members receive all they are entitled to have. All they receive is an admission ticket to the Aquarium Show, while representatives of affiliated societies have the privilege of attending and voting at the principal meetings. As a rule these representatives are anything but horticulturists, whereas the members are mostly Chrysanthemum growers. This makes it look a case of countrymen paying the piper, while the Londoners choose the tune; but I do not blame the idol so much as the worshippers.

Under the present construction of the Society, it is very doubtful if any country grower, however good, has the least chance of being elected on the Floral Committee, therefore under the circumstances it is quite useless offering any names for nomination. What is wanted, and must be had, is a Society and a Floral Committee of widely representative growers elected by ballot; for however honest and *bonâ fide* the transactions of the present Committee may be, it is evident they do not satisfy the general body of the Chrysanthemum world out of London, if in it.

Mr. Dean further supports himself with the idea that the central body must be in a position to know more than outsiders. Next autumn I may be in a position to show the fallacy of this notion. The Beauty of Exmouth case is not settled to the satisfaction of hundreds of countrymen.—J. H. GOODACRE.

THE Secretary and Committee of the N.C.S. ought to be pleased that your correspondents are seeking to improve it by placing it on a wider basis, and thus making it more truly "national" in character. We have been told that most of the principal Chrysanthemum growers are on the Committee. Where are such men as Messrs. Molyneux, Parker, Drover, and many others that might be named? The Floral Committee meet in private, the judges work among the public. I think it should be the other way about. I think Mr. Addison's proposed rule a first-rate one, and if it is not adopted we shall want to know the reason.—A COUNTRY MEMBER.

I CANNOT agree with Mr. E. C. Jukes, page 12, that it is entirely the fault of the country members that a preponderance of metropolitan growers and exhibitors are on the Committee. The country delegates may not be so united in their choice as the "metropolitans," but why do not the N.C.S. adopt the same rule that provincial societies have in force—viz., that the Committee shall consist of a fair proportion of trade and private growers, both metropolitan and provincial? This certainly would do away with the charge of "cliqueism," and the Society would be more fully entitled to be called "National." Referring to the Beauty of Exmouth case, I trust Mr. Jukes does not expect me to believe that the Sub-Committee carried out the injunctions of the General Committee by investigating the matter in the manner they did. Had the Sub-Committee been appointed for the purpose of discussing, "How best to shelve the matter," I do not think they could have acted much differently, and why could they not go into this case without fear of libel, the same as they did in the Wells' case? Now, does Mr. Jukes really believe that most of the leading authorities upon Chrysanthemum culture are on the Committees of the N.C.S.? Mr. Jukes is certainly entitled to his opinion, but many will differ from him. I admit that those most interested in the Chrysanthemum trade belong to it. How fond the officials of the N.C.S. are of pointing to the R.H.S. as a model of procedure. I am not questioning the methods of that Society.—HENRY HAVELOCK.

I THANK you for allowing a free and fair discussion in the Journal, I am sure it will do real good to the N.C.S. in the long run. I adopted the only method I could to make the facts known, and I am heartily pleased to see the way the public appreciate your having opened your pages so impartially.—W. WELLS.

MR. GODFREY'S complaint seems to have afforded an excellent opening to all those persons who have real or imaginary grievances against the N.C.S. to distinguish themselves in print, and the discussion that he

opened bids fair to drift into numerous side issues. I quite believe it to be for the advantage of us all that the Editor should offer every facility for a complete discussion of any genuine grievance that may exist; but the query that has arisen in my mind on reading the correspondence is, Are some of the complaints that have been made well founded? The expediency of holding the Society's Shows at the Aquarium is a perennial nuisance. Every year the question crops up either in the Press or at our meetings; the objectors make no alternative proposition, the same reasons are given why we go to that building, and time is wasted in listening to a complaint which for want of more generous patrons we are unable to remedy. There is, in a word, no company or public body in the Metropolis that offers us the same encouragement to hold our Shows as the Aquarium Company does.

If Mr. Goodacre's letter may be taken as a sample there are one or two curious statements in it that seem to demand an answer. He says we need not exclude the Press from our meetings, by which observation his readers might think that the meetings of the Society are held in secret, which is not and never has been the case. At the Floral meetings acknowledged representatives of the gardening Press are by the seventh regulation of that Committee allowed to be present, and it is rare indeed to find one of those meetings where three or four of the regular staff of the gardening papers are not in attendance. Similarly at the General Committee meetings, ever since the formation of the N.C.S., all the gardening papers of any pretension at all have been represented, and with the exception of one or two of the penny papers who do not report horticultural meetings of this kind, they have given accounts of the business done. If there be a case where for a time a paper has been unrepresented, the fault lies certainly not with the Society or its officials. So much for the Press exclusion.

Mr. Goodacre greatly exaggerates when he says an endless number of certificated varieties are consigned to the rubbish heap after a year's trial by the growers. There are many perhaps that have been pushed aside by newer and improved sorts in the course of a few seasons, but the proportion is not greater than could be expected in the law of progress. Certification is a mark of present merit, not a hall-mark for eternity.

As an amateur who has tried the experiment of importing new varieties direct from the raisers, I do not see how we can expect it to be otherwise than that a large number of certificates should be awarded to trade growers. They certainly do not receive more than their share; and if the same firms' names appear more frequently than Mr. Goodacre approves of, let it be borne in mind that the business of importation to any extent worthy of the name, is carried on within the London radius only by about half a dozen firms at the most. There are few provincial nurserymen that can afford to indulge in this costly branch of business, and as their novelties are usually a year behindhand, of course the original importers stand the best chance of being first in the field with any flower that is new and striking. The number of worthless flowers thrown away by the trade far exceeds anything like the number of certificated flowers discarded by other growers.

In the Beauty of Exmouth case it would be interesting and instructive to know how many of our critics would act in defiance of legal advice; and seeing that both parties are willing to substantiate their sides of the question by sworn statements, the Sub-Committee not being judges or a legally constituted jury, but only ordinary business men, have as much right to give credence to the member complained of as to the one complaining. They, however, in point of fact, do neither, but, pointing out the difficulty that has arisen, recommend no further action be taken. Even supposing a member of the Society were guilty of the grossest irregularity, and proved to be so, there is no rule by which his expulsion could be effected. This to my mind would be the only practical solution in a case where indisputable proof of wrongdoing should be brought home to a member. But before resorting to such a course of action something better than word against word, and stronger than oath against oath, would be required; there ought to be a preponderance of evidence on one side or the other, and not an equality. A review of the correspondence suggests many reflections, but I have perhaps occupied sufficient space for the present.—C. HARMAN PAYNE.

I SEE Mr. Godfrey is dissatisfied with the Chrysanthemum people generally. It reminds me of some people when finding fault with the world, and when such is the case it is rather a pity, in my opinion, they ever had anything to do with it, and must be in a disagreeable position.

The discussion respecting the granting of a certificate to the Beauty of Exmouth is reflecting discredit not only on all those who comprise the Committee and have to carry their duty into effect, but also the Society that elected them. If there is one person in the universe more against, and would at once openly denounce anything discreditable or unfair in working for the public good on either of the Floral Committees with which I have the honour of being associated for many years, it is myself. It was I who asked to have the bloom of Florence Davis brought to the table for comparison with that of Mr. Godfrey's. Why did I do this? Simply because, as there always ought to be, a discussion as to the relative merits of the plants and flowers brought before us. Surely there is nothing wrong in this.

I must say I have a dislike to hearing expressions of undecided opinions, especially on committees. I often hear persons say, "I hardly know whether I like that flower or not." I pity their want of discrimination and decision. In this case two committees differed, and that

difference of opinion brought out the facts, and they acted accordingly. No one now has the slightest doubt of the correctness of the discussions. What on earth can anyone wish for different or better than this? Whatever one of the Committeemen did or said in his business capacity never ought to have been mixed or even mentioned in connection with it. All bartering is quite apart from the functions of the Society. As far as I heard and saw, nothing was said beyond what a member of that body had a right to say. There is nothing to call for an inquiry whatever on the part of the Floral Committee of the National Chrysanthemum Society, and I hope none will be made.

I think I have missed but three meetings since its formation, and if any country member can show that he is better qualified, or has the prosperity of the Society more at heart, and acts more openly and correct (I feel I can also include all my colleagues) than myself, I should be glad indeed to see him acting in my place; he would be just the person wanted to silence all cavils, endow the Society with prosperity, and make it not only thoroughly national, but the "World's" Society, with the greatest possible speed.—H. CANNELL, *Swanley*.

#### PRINCESS MAY.

I ENCLOSE a late bloom of Princess May. What do you think of it for a late bloomer? It is not so large as those produced earlier, still not very small for January.—N. MOLYNEUX.

[The bloom referred to is 6 inches in diameter, with long, partially incurved glossy pearly white florets. It is the finest white Chrysanthemum we have seen at this period of the year.]

#### JOHN LAMBERT ONCE MORE.

WERE it not that Mr. Lambert is so wide of the truth in the insinuation contained in his remark, "That where I judge he finds Golden Queen of England substituted for John Lambert," I should not trouble to occupy space in the Journal in such an idle controversy. My wish when writing to the horticultural Press is to benefit the public and not gratify the personal pique of any individual. Mr. Lambert and I judged together at the last Liverpool Show, and he knows perfectly well that as we found the names so we left them. In answer to the question in Mr. Lambert's last paragraph I may say I adapt myself to circumstances. I am content to abide by the ruling of the N.C.S. catalogue or I can depend upon my own judgment, whichever is required.—E. MOLYNEUX.

I WISH to endorse all that Mr. Hopkins said last week in the *Journal of Horticulture* (page 13) in reference to John Lambert. I have grown that variety side by side with Golden Queen for the last two years, and find it unquestionably the better one. Several Chrysanthemum growers of this district are of my opinion, and I think it hardly fair to the raiser that its superiority is not universally recognised.—J. DOWNES, *Berkswell Hall Gardens, Coventry*.

#### SECRETARY FARSON AND MISS MARÉCHAU.

I SEND you a bloom of a Chrysanthemum, Secretary Farson, which, according to Vaughan's description, should be yellow, thus: "large yellow ball with tubular petals, like L. C. Maderia, but larger in size and clearer yellow." It promises to be a grand variety, but I hardly think it can be styled an incurved, if so, it will be a monster. I also send you flowers of Miss Marechaux, the best white incurved variety for Christmas I have yet met with. I have grown it for about eighteen years, and never found its equal. This variety never mildews like the "Tecks," and the plants can be grown very closely together, as it makes small foliage and wiry stems. You will observe the flowers are not fully out yet.—W. WELLS.

[The bloom of Secretary Farson is of great size, but more of a golden bronze than a yellow. The florets incurve, but more experience is needed to determine its classification. The flowers of Miss Marechaux are charmingly fresh and pure. The variety has long been regarded by many growers as one of the best Christmas Chrysanthemums.]

#### NEW CHRYSANTHEMUMS.

THE ably written notes by Mr. Molyneux are undoubtedly very useful to all Chrysanthemum growers, and are looked for year by year with much interest. Notes coming from such an able cultivator should induce other skilful growers to give their experience, as varieties differ according to the situation the grower may be located in. It is my opinion that this would help to do away with the tediousness of perusing the many lists that are now placed before the public. The following is my experience with a few recently introduced varieties:—

*Flora Macdonald*.—The blooms of this have been rather rough this season, and too late to be seen on many boards, yet it is well worth a place in all collections.

*Oeta*.—This was also too late this year. The plants appear to want stopping the first week in May, for the bloom is a long time coming to perfection even after showing colour. Nevertheless it is a very pretty flower, the colour of a bright Mrs. Coleman, the florets incurving very tightly. It is a good front row bloom; the plant is of rather dwarf habit.

*Ami Hoste*.—This was grand with us during the past season. This should almost dislodge Mrs. Shipman, as it is much like it in colour, and being more than twice as large, deep in build, and well formed, it is good for early shows.

*C. B. Whitnall*.—This seems likely to turn out a good thing; colour

soft velvety maroon; bloom of good form, after the build of Jeanne d'Arc. It should displace Prince Alfred, as it is much brighter. A strong grower of medium height.

*Mrs. Clibran.*—This is a Princess of Teck in form, and much like it in colour when first opening. When the bloom is finished it shows a blush shade, while the outer florets are tipped pink, giving a distinct appearance. The plant a vigorous grower, about the same height as Princess of Teck, but fourteen days earlier.

*Noel Praquell.*—This has turned out fairly good; the flower is of excellent form, though the florets are thin in texture, only fit for large collections. Plant dwarf, about 3 feet 6 inches, rather a weak grower.

*Camille Flammarion.*—This and Robert Cannell have both done well with us, the latter especially so. The bud should be fixed early of both these to secure good blooms. R. Cannell lasted fully a month in good condition.—J. PITHERS.

(To be continued.)

#### FRUIT FORCING.

**Vines.**—*Early Houses.*—Exercise great care in ventilating, as sharp northerly and easterly winds, with cold draughts, injure the foliage, causing it to become stunted and crumpled, but judicious ventilation is essential to sturdy growth and well developed foliage. A confined moist atmosphere, on the other hand, causes the growth to become lean and drawn, the leaves thin and poor in texture, therefore liable to be scorched by the sun and fall a prey to red spider. Attend to disbudding and tying down the shoots before they touch the glass, being careful not to displace them from their sockets or cause them to snap by too sharp bending and too tight tying. Stop the bearing shoots one or two joints beyond the fruit where the space is limited, but where there is room for lateral extension do not confine it to any given number of joints beyond the bunch, extending it so that an even spread of foliage fully exposed to light will be insured, yet avoid overcrowding, as that is fatal to satisfactory results. Remove all surplus bunches, and, when they come into flower, maintain a day and night temperature of 70° to 75°, with a decline, however, of 5° through the night, and a rather drier atmosphere.

*Vines in Pots.*—The heat about Vines in pots must not be allowed to decline, but bring the fermenting materials up to the rims, pressing them down, yet not so as to raise the temperature above 70° to 75°. A heap of Oak or Beech leaves and stable litter should be in the reserve ground, to admit of a supply of prepared material being obtained as required. When the Grapes are set thin the berries carefully, supply liquid manure to the roots, and place some turves, grass side downwards, around the rims of the pots, so as to form a dish, the turves extending over the rims and resting on the fermenting material, and fill the dish with decayed manure. This will encourage surface roots, which will extend to the turves over the rims of the pots and into the fermenting bed, and greatly assist the Grapes in swelling.

*Houses to Afford Ripe Grapes in June.*—There must not be any further delay in starting the Vines intended to produce Grapes at the time named. If the roots are partly inside and outside, the latter border must be protected with leaves or litter, so as to prevent the soil being frozen, but this ought to have been attended to in November. Supply the inside borders thoroughly with water in a tepid state, and if the Vines are weak follow with liquid manure—rather thick, but not too strong. Sprinkle the rods twice a day, depressing young rods and canes to a horizontal level or below, so as to insure the buds breaking evenly. Maintain a temperature of 50° to 55° at night and on dull days, advancing to 65° from sun heat, continuing those heats until the buds begin to swell, when gradually raise the night temperature, so as to have it 60° by the time the Vines come into leaf, and to 65° by day artificially.

*Vines from which the Grapes have been Cut.*—The sooner the Vines are pruned now the less danger is there of their bleeding from the wounds when the sap rises. It is a good plan to dress the cuts with styptic or knotting whilst they are dry, so as to close the pores of the wood, as a safeguard against bleeding. Cut to a plump round bud as near the base as possible, two buds being sufficient to leave where the wood is stout and short-jointed, but where the practice has been followed and not proved satisfactory the operator may prune to the best bud on well-ripened wood. This will cause the spurs to become long, and a shoot must be trained from the base to displace each spur after its shoot has borne fruit. Thoroughly cleanse the house, washing the glass with clear water, the woodwork with soap and a brush, limewash the walls, and remove the loose bark from the Vines, avoiding peeling and scraping that may injure the live bark, and wash them with soft soap, 4 ozs. to a gallon of water. Surface-dress the borders, clearing off the loose surface, using fresh loam with a 9-inch potful of steamed bonemeal to a barrowload of loam. Keep the house as cool as possible to secure complete rest. If there are plants in the house only afford fire heat to exclude frost, not exceeding 40° to 45°, by artificial means.

*Late Grapes.*—These are best cut with all the wood that can be spared, and the ends of the shoots placed in bottles of rain water in an

inclining position in a Grape room, dry fruit room, or an empty room from which frost is excluded, but not warm (above 50°) or the Grapes will shrivel. This will admit of the Vines being pruned and the house being cleaned, and is much better than allowing the Grapes to hang on the Vines, pruning having to be deferred until a late period, whereby the latter are liable to suffer through bleeding and want of rest. Maintain a mean temperature of 40° to 45°, with a dry atmosphere in houses where Grapes are hanging, and avoid a close atmosphere when the weather is favourable for ventilation. Examine every bunch frequently and remove all decayed berries.

**Pines.**—*Fruiting Plants and Starters.*—The temperature must now have a mean of 70°, 5° less on cold nights, and 5° more on mild dull days, admitting air at 80° with sun heat, but not lowering the temperature, allowing it to rise to 85°, and closing at 80°. Sprinkle all available surfaces twice a day, but do not syringe the surface of the bed between the plants, and avoid producing dense steam by damping highly heated hot-water pipes. Syringe the plants lightly occasionally early in the afternoon of fine days when the axils of the leaves become dry. Examine the plants twice a week for water, and supply it only to those in need, always in a tepid state, and with a "dash" of guano in it, say 1 lb. Peruvian guano to 20 gallons of water.

*Pines for Successional Fruiting.*—Another batch of Queens should be started early in February to supplement the supply of fruit from those plants which are already introduced for ripening in May and June. Enville is an admirable variety for starting at that time, and affords even-sized handsome fruit with a moderate crown. The plants selected must have a stout base and opening somewhat in the centre of the leaves. Plants that have completed a good growth in the previous summer, and have been kept rather dry and cool for a period of six to eight weeks before starting, are most likely to throw up fruit promptly. Beds that have bottom heat supplied by hot-water pipes can be soon prepared for the reception of the plants. Where, however, the heat is afforded by fermenting materials, the necessary steps must be taken at once to get the requisite beds made, and 85° to 90° of bottom heat secured by the time required. Plants that have been kept somewhat dry preparatory to starting must have the soil properly moistened before the pots are plunged in the bed. Successional stock will be suited with a night temperature of 60° to 65°, 5° less in severe weather, and 5° to 10° more in the daytime, ventilating moderately when the weather is bright and mild, avoiding drying currents.

#### THE KITCHEN GARDEN.

**Forcing Cauliflowers.**—Cauliflowers will not stand hard forcing, but the Early Dwarf Forcing or Snowball can be forwarded considerably, or be had fit for use from the middle of April without much trouble. If a stock of plants are already raised this will be a further gain of a fortnight or more, otherwise seed should be sown thinly in pans or boxes, and placed in gentle heat. Directly the seedlings appear transfer to a shelf near the glass in a warm greenhouse or pit, as they draw up badly in strong heat, also breaking down wholesale if syringed. When well into rough leaf put singly into 3-inch pots, keep rather warmer till rooting afresh, when they ought again to be near the glass in gentle heat, a heated pit answering well. Before they become badly root-bound the plants, whether autumn or winter raised, should be finally planted out in a deep frame or pit, and not less than 15 inches apart each way. Given the benefit of a mild hotbed of leaves and manure, and a foot of rich loamy compost, they will grow strongly, and must be freely ventilated, or otherwise they will become too tall. Being kept well supplied with water and liquid manure it is surprising what beautifully white and serviceable hearts will be produced. A good succession will be had by planting on slight hotbeds with only rough frames and mats by way of protection, these batches, as a rule, hearting in before any grown in handlights.

**Forcing Peas.**—Peas again will not stand much heat, but may be forwarded considerably under glass, and either in long, narrow, deep boxes, pots, or planted out in pits. They are not particularly remunerative, or not nearly as much so as Cauliflowers, though early dishes are always appreciated. Chelsea Gem and William Hurst are suitable for house and frame culture. The earliest gatherings can be had from plants grown along the fronts of newly started vineries and Peach houses, those in frames forming a good succession, and also, as a rule, producing the best crops. Chrysanthemum pots are admirably adapted to Pea culture, and fully fifty of these should constitute a batch. Well drain and three parts fill with good loamy compost, to which a sprinkling of wood ashes has been added. Sow the seed rather thinly, cover with 1 inch of soil, and water if at all dry. Keep them in the light position indicated or on shelves, water sparingly till the plants are growing strongly, then let them never approach dryness at the roots, liquid manure also being needed when they have reached the flowering stage. Thin out the plants early where crowded, and support with Birch or other spray, or sticks and raffia. Make a second sowing a fortnight later on, and also sow several flat boxes with seed of the same variety, with a view to having them in readiness for early planting out in frames or pits.

**Potatoes in Pots.**—These would succeed well under conditions that have been already named as suiting early Peas. The Chrysanthemum pots or any 9-inch or larger in size also suit Potatoes, one strong set going to the size named and three to larger pots. The Old Ashleaf, Early Border, Sharpe's Victor, and Mona's Pride are among the best varieties for pot culture, but if neither of these are available then Veitch's Improved Ashleaf may be substituted. Select strong seed tubers, rub off all side shoots, leaving the central sprout only. The best progress will be made if these seed tubers are set closely together,

sprout end uppermost, in shallow boxes and placed in a Peach house or vinery being forced. The warm moist atmosphere will cause them to grow strongly, and when side roots show at the base of the sprouts the time for potting has arrived. Plant them rather deeply, allowing good room for top-dressings. Also start enough sets at once, and in a similar manner to plant a two or three-light frame or a whole pit, and which should be got ready for them in the meantime.

#### PLANT HOUSES.

**Palms.**—During severe weather, when an excess of fire heat has to be used to maintain the desired temperature, thrips are liable to prove troublesome to these plants. A sharp look out must be kept for these pests, for if allowed to become established they soon injure the foliage, which may look unsightly for years. Once these insects make their appearance, sponge the fronds carefully with a solution of tobacco water in which a little softsoap has been dissolved, say 1 oz. to four gallons. After all have been sponged, fumigate the house once or twice in succession until every trace has been destroyed. Where these plants can be liberally syringed once or twice daily according to the weather, they can, as a rule, be kept free from thrips, but where the syringe cannot be freely used constant care and attention is needed. Do not overwater these plants at their roots, and, on the other hand, be careful not to allow them to become dust dry, or the foliage will soon present a sickly appearance. Maintain a night temperature of 60° where Kentias and other warm kinds are grown.

**Adiantums.**—Plants from which fronds have been gathered, and only small stuff remains, may be cut clean over and started again into growth. If placed in a temperature of 55° to 60° they will soon commence pushing up new fronds, when they should be repotted without delay. If the plants need larger pots remove the drainage and any roots that may be crowded about them; the remainder of the ball can be placed in the new pot without disturbance. If the plants are in pots large enough they may be divided by cutting them straight through the middle; the drainage should be removed and the plants potted without disturbing them further. The soil, which should consist of equal portions of good loam and leaf mould, with the addition of sand, must be pressed firmly into the pots. If the plants have been infested with small slugs thoroughly dust the crowns with soot. This will drive them out, and they can be picked off a short time afterwards. Continue this practice until the plants are perfectly free from these pests. A small white caterpillar-like grub occasionally infests these plants and feeds upon the crowns and young fronds just as they form to such an extent that seldom a perfect frond is allowed to develop. These can only be destroyed by thoroughly shaking away from the plants every particle of soil, when they roll out and can be destroyed. The best means of stamping them out is to burn any infested plants. After potting stand the plants on a moisture-holding base and syringe freely amongst the pots. Very little water will be needed until the plants commence to grow.

**Gloxinias.**—Any plants that are starting into growth where they have been stored away to rest will only draw up weakly if allowed to remain in a semi-dark place. The old soil may be shaken from the roots and the tubers soaked for a short time in tepid water and then left to drain thoroughly. After this they can either be potted singly or placed in boxes amongst leaf mould and sand until they have well started into growth, when they can be potted singly into the pots in which they are intended to flower. Once the plants are started in pots we find they do well on a shelf fairly close to the glass, where the temperature ranges from 55° to 60°.

**Eulalia japonica.**—Plants that died down after use in the conservatory and have since been kept in a cool house may be removed to the forcing house or any structure where gentle warmth is maintained. They will soon commence to push up new growths, when the plants may, if increased stock is needed, be divided into two, three, or more pieces according to their size. These plants are most useful in 5, 6, and 7-inch pots, and grow freely in any rich soil—good loam, sand, and one-seventh of manure will suit them very well. If gentle bottom heat can be given them after division they will soon become established, when cooler treatment will suit them well.

**Begonia weltoniensis.**—This is a useful plant for conservatory decoration, as well as two or three other kinds of a similar nature. The earliest batch may be shortened back and placed into a temperature of 50° until they show signs of growth, when the old soil should be shaken from their roots and the plants repotted in a fresh compost. The plants can be placed in the same size pots or smaller. If the latter, they will soon need repotting. They will be found to succeed well in three-parts of loam to one of leaf mould, with a liberal quantity of sand according to the texture of the loam, and one-seventh of old Mushroom bed refuse. Water with care until the plants are growing freely. They will start well in a vinery if no better position can be found for them.

**Caladium argyrites.**—A good batch of tubers should be started into growth; 2-inch pots are large enough in which to start them, or better still, place them in pans amongst light sandy soil, and after growth has commenced put them in pots. The pans or pots containing the tubers should be plunged amongst cocoa-nut fibre refuse in the propagating frame. Too much water at first often proves detrimental to them.

**Poinsettias.**—As the bracts of these fade place the plants where the temperature ranges about 50°, so that their stems may harden and ripen. Keep them on the dry side, and after a short time they will not require any water.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

WE are still frost-bound. About 2 inches of snow fell on January 3rd and 4th, and on the 5th the thermometer registered 9°. At no time during my lifetime has there been so much frost during October, November, and December as we experienced last year. Several times we have had an unbroken frost of three months' continuance during January, February, and March, but never in the latter months of the year.

#### OBSERVATIONS.

It is very desirable that bee-keepers should pay particular attention to bees from the time they are put up in autumn until they are past danger in spring. The condition they are in at the start, how they are protected, and their state at the end of winter should be carefully noted, also noting the numbers of bees the hives may have lost, or whether the hives are actually stronger at the beginning of March than they were at the beginning of November, as is not unseldom the case. A diary of the state of the weather is similarly desirable, not only to the apiarian, but to the worker in the garden. No two winters are entirely alike, but by collecting data of that nature over a series of years the notes become valuable for reference. If bee-keepers would in due time state how their bees have wintered on the points indicated, the record would be interesting and suggestive. That some bee-keepers have something to learn there can be no doubt. When one person can winter bees (no matter how old they are) without much, if any, loss, while others have many dead bees blocking up the entrances of their hives, necessitating removing them with a "hooked wire," so as to save the remnant of a once strong hive, it is clear that more light is needed—more sound practical knowledge. Advice is often taken from teachers who simply give the best they can, and when a calamity occurs amongst the bees of their pupils take refuge in the proposition that the bees died from old age. In nine cases out of ten this, in my experience, is a mere fallacy, and my advice to the inexperienced is to rely on the most successful workers in the practice of the apiary as the safest guides.

#### WHITE LUPIN FOR BEES.

Some people object to growing this plant owing to its liability to shed its flowers, supposing it to be natural. This is not the case. It is due to insects. The white Lupin, in addition to its beauty, secretes much honey, and exudes it in great quantity from the flower stalk, standing in large clear globules. The bees gather this honey, as also do earwigs, and thus destroy the blooms.

#### ARE BEES A NUISANCE?

I SHALL be greatly obliged if you can answer the following questions:—1, Are bees one of the specified "nuisances" of English law? 2, Has a case ever occurred where neighbours have obtained an injunction from a magistrate or county court judge to compel a man to remove or sell bees located on his own ground owing to them occasionally stinging people during hot weather, or damaging a neighbouring laundry business by soiling the clothes during their cleansing flights in spring and early summer?—F. S.

[Bees are protected by law. A nuisance means an "unlawful act or omission." It is not unlawful to keep bees, but if bees are so irritated as to attack people in the public streets or thoroughfares town or county councils might be compelled to frame local acts to prevent the annoyance. If bees are handled and kept as they should be they will sting no one outside their boundary, and it is to be hoped bee-keepers will so manage their apiaries as to make extreme measures unnecessary. Cases have been tried in America, and even in England, to prove bees a nuisance, but in no instance did the pursuer get a conviction. May not a laundry, in some respects, be a greater nuisance than bees?—A LANARKSHIRE BEE-KEEPER.]

#### THE TITS AND THEIR HABITS.

MR. S. ARNOTT (see page 18) will please observe that it was the blue tit, *Parus cœruleus*, which was accused of taking the fruit buds and killing the bees. I have already alluded to the habit of *Parus major* picking up dead bees and dissecting them. Since the snow came, which now lies about 6 inches deep where not drifted, I have watched the great tits constantly peering around two stocks of bees in straw skeps near a window convenient for close observation, but they have not interfered with the hives by tapping or otherwise. I have suspended a lump of suet for their benefit, and they appreciate it. No bird is easier caught than these. In

trapping bullfinches these birds (*P. major*) are a nuisance by entering the cages. I invariably give them their liberty. A lump of suet is an irresistible bait.—J. HAM.

#### PUNIC BEES AND COLOURED COMBS.

I DID not intend to say anything *re* "C., Northumberland," (page 558) until others had had a say, as I was completely puzzled, not having heard of or seen a case where Punics sealed their combs "yellow." Of course I naturally thought this yellow was due to propolis, but the latter explanation of "C." clearly shows that it was not the cause. I have one theory to account for it, which may or may not be correct, which seems to have escaped our friend "A.L.B.K.," which is this: when bees are working on some kinds of flowers, Sainfoin for instance, all the wax they make is a very deep yellow. I do not know if Punics can make white wax from this source, but every other race seals Sainfoin honey with very golden yellow sealing. Other sources, such as the Dandelion and Black Currants, produce yellow wax; in fact, every honey seems to yield wax of a different colour, which to me is a mystery. Why is this difference in colour? Is it pollen, or what?

Now I know Punics will work on anything that will yield any sweetness, even if neglected by any other bees, and they will also travel a greater distance to collect it, hence it seems to me that the bees simply got their stores from a source neglected by the other bees, either by working on a source neglected by them, or by going a greater distance for it, and the fact that they sealed honey both in supers and body of the hive shows they were not to be despised.

Some time ago I received a query on this very subject from a lady in Northumberland, who intimated that she intended asking it in these pages. Being puzzled, I thought it best to see what the public had to say, as some infer that these bees soil their combs with propolis, which I deny, not having seen or heard of a case, even with hybrids. The bees of "C." are hybrids. What interests me most is the fact that "C." makes it clear that propolis is not the cause of the yellowness of sealings.

I may here say that if "C." or anyone else who have had these bees from me are dissatisfied with them, they have only to apply for their money back. Mr. W. H. Ley of Easton, near Stamford, averaged 140 lbs. of honey from his Punics and 40 lbs. from natives (British) the past season; figures like these tell their own tale. His British bees were from queens of my breeding, while many of his neighbours got no honey at all from their English bees.—A HALLAMSHIRE BEE-KEEPER.

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (W. B.).**—Some of the works mentioned are, as you probably know, published at this office. We will send your letter to our correspondent, and he may write to you on the subject. The last work you name would not be of substantial value, and you could employ the somewhat large amount to better advantage.

**Address of Correspondents (M. C.).**—It is hopeless for readers to expect editors to supply the names and addresses of correspondents who do not send them for publication. We have sent your card to the writer to whom you allude in case he may like to communicate with you. That is all we can do in the matter.

**Scale on Vines (R. R.).**—Judging from the dried leaves sent the Vines must be in a deplorable state. You did right in taking off the infested leaves and burning them, also in washing the house and Vines. We should not paint the rods with anything, but dress them with a petroleum emulsion, such as is advised on page 16 last week for destroying American blight on fruit trees, but half the quantities of soft-soap and petroleum there recommended would be safer for the Vines,

and a temperature of 120° would destroy all the scale insects covered. You must be very watchful in spring and prevent anything like such an incrustation as occurred last year. You will master the scale with perseverance. The Vines must have sustained serious injury.

**Prize Medal Essays (E. A. W.).**—The names of gardeners to whom silver medals have been awarded have been published. We repeat them—Mr. T. Garnett, Mr. E. D. Smith, and Mr. G. A. Bishop. We shall shortly announce the names of other medallists for essays now under adjudication.

**Liquid Ammonia from Gasworks (J. E.).**—We presume the liquid ammonia is the "gas liquor" from which sulphate of ammonia is manufactured; if so, it must be used very carefully, and highly diluted with water. For vegetables it may be used at strengths corresponding to the vigour of the plants, about 1 pint to a 3-gallon water-potful of water being quite strong enough when it is used over the foliage, and in some cases it will brown the plants at that ratio, not only because the foliage differs in hardness, but through the variability of the strength of the gas liquor. For pouring between the rows of growing crops it need only be diluted with six times the quantity of water, and is valuable for all the Brassica tribe and Peas, taking care not to apply it to their stems. For fruit trees it should be diluted with ten times the quantity of water, and be applied during the swelling of their crops, preferably in the first half of their swelling, as given late it has a tendency to induce late growths. It will benefit every kind of plant that needs support, only take care to supply it weak, and to pour it clear of their foliage. It, however, requires to be used with care, as an overdose is fatal.

**National Chrysanthemum Society's Catalogue (H. R.).**—As intimated on page 18 last week, we sent your letter to Mr. Richard Dean, the Secretary of the N.C.S., who replies as follows:—"This matter is readily explained. Mr. Richardson wrote for a catalogue and said he had enclosed a postal order for 1s., which was not in his letter. I sent him a supplemental catalogue, and asked him to return 6d. in postage stamps. Then he writes on a post card to say I had made a mistake, that he did send 1s., and that he wanted the larger catalogue. His post card contained no address, and, unfortunately, his previous letter had been destroyed, and I could not refer to that. I now send him the Centenary catalogue, but I have not received a single penny for either. If he enclosed the postal order it must have been abstracted during the transit. I give an official receipt for every sixpence sent for a catalogue. If Mr. Richardson's order had been received my receipt book would have shown a counterfoil to that amount, but there is none." It appears that at the time Mr. Dean wrote the above, instead of his (as alleged) owing you sixpence, you owed him eighteenpence. Whether the amount has been remitted or not, you will admit he has met the case fairly.

**Eucharis Failing (G. S.).**—Your plants are no doubt infested by the bulb mite, or what is so commonly termed the Eucharis mite. To clean the plants and restore them again to health and vigour has baffled the skill of many an expert in plant culture. We, however, advise you to try and clean them. It is unfortunate that you turned the plants out of their pots before you could give them gentle bottom heat to again start them into growth. You must go over the bulbs, and remove all decayed portions carefully. The three outer scales of the bulbs have been removed in some instances. In your case it may be necessary to remove one or more, then wash the bulbs thoroughly in tepid water, but before doing so remove every portion in which these mites can secrete themselves. After washing lay the bulbs in dry sand to harden the outer scales in order that they can bear a stronger solution of insecticide, in which they should be well dipped. Any favourite insecticide will do, and may be used the strength that would destroy aphides (green fly). Eucharis bulbs take a good deal of killing, but the process of cleaning will weaken them, and after they are started again the feeblest of growth only will result. Some cultivators have claimed the eradication of these pests by a free use of lime water, which is well worth trying also in your case. Others by the use of an insecticide that is advertised and sold for the purpose. The soil at first should at any rate consist of good rich loam and sand. For years we have used nothing else for Eucharis.

**Large Tomatoes (E. G. N.).**—The variety Royal Sovereign about which you inquire was exhibited at the Drill Hall on July 26th, 1892, by Mr. R. Gilbert, Burghley Gardens, Stamford, and received an award of merit from the Fruit Committee of the Royal Horticultural Society. It is an American introduction, and we believe catalogued in the United States under the name of Ponderosa. Most probably it is the heaviest fruited variety in cultivation, the six fruits shown by Mr. Gilbert weighing 10½ lbs., and it is possible to grow them still larger. As may reasonably be conjectured, the fruit are very solid, and the flavour is good. All the same, it will never be extensively grown unless prizes are offered for the heaviest Tomatoes, irrespective of form and colour. Royal Sovereign is far too coarse, and the colour, pale red, is also objectionable. The fruit sets freely, and if the flowers with fasciated pistils are pinched off early some moderately large well-formed fruit may be had. For exhibition purposes no variety surpasses a good stock of Perfection. Grow this strongly and sturdily, pinch off the first unshapely flowers as advised in the case of Royal Sovereign, fertilise those reserved, avoid overcropping, feed plants well at the roots, and plenty of perfectly formed richly coloured fruit will be had, or such as will win prizes. If after reading this you still have a desire to grow Royal Sovereign with a view to winning prizes write to Mr. Gilbert for his price list of novelties.

AT no time of the year is the decorating of apartments with plants and cut flowers of so much importance as at the present season, when everything out of doors is dull and colourless, and when it is all the more needful to have rooms as bright and cheerful looking as possible. There is now little difficulty in procuring suitable material. So many plants are adapted for the purpose, and the cultural details are also generally so well understood, that, paradoxical as it may seem, the chief drawback in many cases appears to be in the production of too many things. In most private establishments the glass erections are not so overwhelmingly extensive as to allow one to grow flowers at discretion; consequently, where a long winter season has to be supplied with plants and flowers there is not much (if any) room to spare for the growing of anything which is not strictly useful. Happily the most useful is also the ornamental, so that in growing a few plants extensively one produces much beauty without losing the useful.

Anyone who has a number of living rooms to furnish with flowers will know how they vary in adaptability. Some rooms are so dark and hot that a few days, at the longest, destroy the majority of plants and flowers. Other apartments so well meet the requirements of vegetable life that both plants and flowers last for very long periods without requiring to be changed. There is also a certain elasticity about the plants themselves which cause them to stand for a longer or shorter period, according to the condition they may be in. One point well worth considering is to study the kind of plants suited for certain rooms, and as far as possible to use these alone. Generally a distinction in the kind of plants or flowers employed in different apartments is commendable, inasmuch as it does away with any sameness in the decoration of the house as a whole.

In the details of watering plants it is necessary to exercise judgment. In some cases isolated plants may stand for several days and not require water. In other instances plants will require watering every morning, and where heated pipes run close past any plants it will be found necessary to give water oftener still. Taking the last mentioned case first, the best method is to place the pot in a saucer, ornamental or otherwise, and each morning to fill this saucer with water. For several years past I have made a rule to apply warm water to all plants in apartments. If the soil is dry warm water passes very rapidly through every portion, and there is no danger whatever of over-watering. Tulips and other soft-growing plants become dry much more quickly at this season than later in the year, when less fire heat is needed in rooms; and for the same reason it will be found that the stems of cut flowers just now absorb water out of the vases much more quickly. A good plan is to cut the flowers the day before they are wanted and to stand them in water until the next morning. By this method the stems absorb less water after they have been arranged.

I have seen many ways of arranging flowers, and several methods recommended for the keeping them quite fresh as long as possible. But so far I have found nothing better than pure water. But while that is so it is remarkable that assistants have invariably to be taught to keep the receptacles clean. If the flowers are fresh when cut, the receptacles clean, and the water also clear and pure, no better means of keeping flowers fresh can

be had. An easy way to clean dirty glasses and earthenware vases will be found in the use of a little coarse sand amongst lukewarm water. The sand makes them absolutely clean. I have tried switches, ranges, cloths, and sponges, but not one of these is so good, so simple, and withal so efficient as coarse sand. Another thing worth mentioning with regard to cut flowers is this: flowers cut with long stems, especially if the lower portion of the stem is hard, do not stand good so long as those cut with short stems. Therefore it is a saving method to arrange flowers at this season with as short stems as possible. With Callas this does not matter, but with other flowers the above remark applies.

Having said so much about routine, the plants and flowers to be used have now to be considered. The number of plants suitable for general employment in the everyday embellishment of apartments at this season of the year are not numerous. There are, of course, Palms; Kentias, *Cocos flexuosus*, *Areca Baueri*, *Chamaedorea*, *Rhapis flabelliformis* are the sorts in everyday use, and for special occasions *Latania borbonica*, *Phoenix dactylifera*, *Cocos Weddelliana*, and *Thrinax elegans* are sorts most in demand. Bamboos are also good; *Metake* and *nigra* the two sorts I prefer. The latter is quite hardy and may be used along with *Aspidistras* in the very worst position. *Pandanus Veitchi* is very good. It stands well, and makes one of the best vase plants we have. Very pretty also is *Phrynium variegatum*, but this does not stand harsh treatment. However, for special occasions, along with *Crotons* and *Dracenas* with coloured leaves, it is worth attention. The common *Ficus elastica* is of the greatest value. Good plants should be at least 4 or 5 feet in height and in 6-inch pots. The variegated form is equally amenable to the discipline of house furnishing, and it is very much superior. We have in constant use several plants of both of these. Plants of *Asparagus plumosus* raised from seed twelve months previously are capital for grouping; so also is the common *Maidenhair Fern*, a plant which stands exceedingly well, and one which always pleases. All required for room decoration must have finished growth in a cool airy house without much atmospheric moisture. Treated thus it is wonderful how well and how long the plants remain in good condition even in unsuitable apartments.

Plants in flower include Tulips, which have been in good condition for several weeks past. The scarlet *Duc Van Thol* is by far the best. I have tried several forms, but not one comes up to this for early work. Then *Lily of the Valley* is indispensable just now. This is quite easy to have in good condition. Of Hyacinths *Charles Dickens*, *Norma*, *La Tour d'Auvergne*, and *Homerus* should be grown. Cyclamens are very good for house work. Suttons' "Butterfly" (white) is, I think, quite the best I have yet seen for this purpose. Very useful also, though common, are *Marguerites*. Plants rooted in early summer and kept rather dry during winter flower fairly well, and stand the heat of rooms much better than if they had been grown in a warmer and moist condition. I like *Zonal Pelargoniums* very much for this purpose. If the plants are changed every week they keep for a long time in good condition. In the way of colour—whether in pink, white, blush, or shades, or red—nothing can be better. Of double varieties *F. V. Raspail*, *Mons. Bruant* (soft scarlet), and *Hermine* (white) are, I think, the best. Of singles there is an endless variety. *Constance*, *Lily*, *Rev. H. Harris*, *Sissie*, *Brilliant*, *Stanley White*, and *Henry Jacoby* are varieties which we have had in good condition all through the winter. Callas are at all seasons most acceptable; just now they are specially so. They do in any position, and if properly treated the same plants flower throughout the season. *Chrysanthemums* are now getting over, but this year they have been less difficult to secure than in most years. *Miss Mary Anderson*, *Avalanche*, *Peter the Great*, *Guernsey Nugget*, *Princess Teck* we find specially suited for late use.

Orchids are generally employed for parties alone—such sorts, for example, as *Odontoglossum Alexandræ*, *O. Rossi majus*, and

*Lælia anceps*. *Calanthe Veitchi* and *C. vestita* do in rooms as well as any other plant.

Flowers for cutting include a variety of *Chrysanthemums*, such as *Mary Anderson*, *Golden Star*, both singles, *Source d'Or*, *Avalanche*, *Princess Teck*, *Miss Annie Lowe*, *Lady Margaret*, *Massalia*, *Elaine*, *Ethel*, and *Mr. Jones*. Perfectly fresh flowers only should be cut for furnishing vases in room decoration. *Zonal Pelargoniums*, *Lily of the Valley*, *Tulips*, *Roman Hyacinths*, *Bouvardias* red and white, *Chinese Primulas*, *Cyclamens*, *Marguerites*, *Callas*, with *Croton* and *Dracæna* leaves, are among the chief things for cutting at present.

The fashion for table decoration has come round to much simplicity, and that allows for a good deal being effected with the outlay of a very little material. A few dozens of *Chrysanthemums* are sufficient for a very large table. As the blooms are now below the medium size these are best arranged in small glasses or silver vases. A very pretty arrangement is secured with white and pink *Primulas* laid on the cloth, at the same time employing a few good leaves of the same plants. Another method of arrangement may be effectively employed, all the material coming from out of doors. Long sprays of one or other of the fine-leaved *Ivies*, with *Rose heds*, bracken Fern of various shades of brown, the common *Polypody* and berries of the *Strawberry Trees*, combine to furnish a charming arrangement. Where *Orchids* are plentiful a few of these laid on the cloth, in combination with *Croton* shoots of the *angustifolium* type, and *Smilax* produce a very rich effect; plants of *Crotons* should be employed at same time. As a rule the one thing to guard against is the using of too much material. A very few good flowers are much to be preferred to lumpy masses.—B.

## NATIONAL GARDENING SOCIETIES.

THOSE who are interested in the controversy now appearing in these pages regarding the doings of the National *Chrysanthemum* Society have doubtless had other thoughts arise in their minds. This, at least, has been the case with me. The whole question referring to the management of so-called "national" societies is both wide and deep, and affords much food for meditation. A decade or so ago "national" gardening societies could have been counted on the fingers of one hand without difficulty, and therefore they did not give rise to much thought. Now, however, matters are changed. At the present time there are at least eight societies, affecting horticulture in various phases, that sail under "national" colours. Many of those, too, have assumed such gigantic proportions, and influence gardening in a more or less degree, that one might well consider the legitimacy of using the term "national." In some respects it is gratifying to know that national societies have grown so rapidly, inasmuch as it augurs well for the future of horticulture; but the various organisations should not in their days of success forget the original objects they had in view. I say original advisedly, because it seems to me, as it might do to others, that some of the societies are inclined to drift away from the purpose for which they were instituted. In other words, do they fulfil the requirements of all their members, and prove themselves truly "national?"

Obviously this is the view in which many country members regard the National *Chrysanthemum* Society. Here we have a Society that has had an unchecked career, and, if we except the small cloud that recently appeared on the horizon, all connected with it have been satisfied. There are upwards of 700 members on the books, and ninety-four affiliated societies in all parts of the country, so from a numerical point of view none can deny its legitimate right to be termed national. But on considering other matters one cannot be surprised at a little disaffection among country members. These pay their annual subscriptions. What do they get in return? Probably a schedule and a pass to the Exhibitions. They should in addition at least have a voice in the management of the Society. The by-laws and regulations affect hundreds of exhibitors in different parts of the country, and therefore it is only right that they should be considered. I am alive to the difficulty in regard to country members. As has been notified in the *Journal of Horticulture*, and as Mr. E. C. Jukes pointed out at the annual dinner, and since in these pages, country members are cordially welcomed at the meetings. Affiliated societies, moreover, had a right to send representatives to the Committee meetings, and it is entirely their own fault if they do

not enforce this privilege. So far so good; but what about expense and time? A remedy is undoubtedly needed.

Passing on we come to the National Rose Society, which has had a spotless and most successful career. There are, according to the annual report printed in a recent issue, 527 members and thirty-six affiliated societies. In addition to these gratifying facts there is a substantial balance at the bankers. Matters could not, in this respect, be more satisfactory. But here comes the inevitable question, "Is it 'national'?" At the annual general meeting held recently it was hinted that of the 527 members no less than 75 per cent. were southerners. This is astounding. A truly "national" society should have a more equal distribution of members. At the meeting alluded to the Rev. J. H. Pemberton strongly appealed to those present to consider the interests of the northern growers, and so make the Society national, but his proposition was rejected. He is unquestionably on the right track, and may he persist in his good intentions until the "prize" is won. Another item worth recording is, that a gentleman at the annual meeting expressed the opinion that were the National Rose Society to consider the interests of northern growers more there would be as many members in the north as there were now in the south. This should be borne in mind.

Then there is the National Amateur Gardeners' Association—a Society that has made great progress. Like many similar organisations it started in a very humble way only two years ago: but it was planted on good soil, and has flourished accordingly. There are now, I believe, upwards of 400 members on the books, a branch Association at Liverpool, and several affiliated societies, including one in Tasmania. These facts speak well for the Association, and affords ample proof that amateur gardeners when properly organised can form themselves into an influential body. The objects of this Association are to watch the interests of "amateurs," the true definition of which is too frequently misconstrued. That this Institution was needed is exemplified by the rapid progress it has made, and it is gratifying to record that the Executive indirectly approached the Royal Horticultural Society in regard to the correct definition of "amateur" with satisfactory results. Besides those mentioned there are the National Auricula Society, the National Carnation Society, the National Dahlia Society, National Pink Society, the National Tulip Society, and so far as I know there may be more that attach "National" to their titles—in some cases perhaps indiscriminately.

Now comes the question as to the advisability of making necessary changes to admit of the term "national" being used in its proper sense. There are difficulties in the way, but if persisted in they can be overcome. The various societies desire the support of country members, and in return, I maintain, that the latter, as already said, have a right to assist in the conducting of the affairs of their respective "national" societies. How can this be brought about? Admitting the fact that London is the centre of horticulture, it does not necessarily follow that the "national" societies should be conducted exclusively by members who reside in and near the metropolis. Indeed such a state of affairs is, in my opinion, most undesirable. At the general meeting of the National Rose Society the Rev. A. Foster Melliard made an attempt to avert this difficulty by making a proposition that country members be allowed to vote by proxy. But the metropolitan element proved too strong, and the proposition, admirable in its way, was rejected. The same idea should be persistently brought forward at all meetings of all so-called "national" societies until the country members obtain their rights and are placed on an equal footing with those "near home." Similar views may be advanced in regard to the exhibitions. A national society should endeavour to please the whole of its members, country and otherwise, by holding a "national" not a metropolitan or local exhibition. What would members of the Royal Agricultural Society say if their annual Exhibition was always held in London? If this organisation can migrate, so to speak, with satisfactory results, could not a "national" horticultural society do similarly? At all events this and other matters are worth considering, and the sooner it is done the better.—OBSERVER.

## EDUCATION IN GARDENING.

SILVER MEDAL ESSAY. (Concluded from page 524.)

### BOOKS TO CONSULT.

THE subjects mentioned in this essay as being desirable of attention by the horticultural student necessarily require a supply of books dealing with the knowledge recommended to be acquired. As orthography was the first subject mentioned, it is necessary to indicate the best book to consult where aid is needed. For ordinary reference to correct deficiencies in spelling, "Nuttall's

Standard Dictionary" is one of the best. Useful and practical books on grammar and composition are "Lennie's English Grammar" and "Currie's English Composition." There are many other useful works on these subjects; indeed, it would not be easy to go far wrong whatever work is selected.

Botany is well furnished with exponents who endeavour from various points of view to inculcate the principles of the science to the student. Much elementary information can be gathered from Dr. Hooker's primer on "Botany," or Professor Bentley's similar primer on the same subject; following the mastery of the contents of these by proceeding to the use of Professor Oliver's "Lessons in Elementary Botany," which is recommended by Dr. Hooker himself, who says it goes over the same ground in more detail. A better little book than Professor Geikie's primer on "Geology" could not be recommended as an elementary book on the subject. It is written in an interesting and simple manner, giving a very attractive garb to a science that ought to be more widely known among horticulturists.

A knowledge of elementary chemistry is a valuable aid to a gardener, but it is not within the range of everyone to study it systematically, as being an experimental science it requires scientific apparatus and leisure. Acquaintance, however, can be made with the results gained by those who have studied the science in the interests of agriculture and horticulture and much information derived. Professor Johnston's "Catechism of Agricultural Chemistry," edited by Professor Voelcker, will furnish the student with an interesting epitome of chemistry, or he can consult with much benefit Kane's "Elements of Chemistry." Gill's "Geometry" will teach all that is desirable or necessary for a gardener to know about that art.

As a valuable reference book for ascertaining the correct nomenclature of plants, their genera, species and varieties, there is none to equal Johnson's "Gardeners' Dictionary" as a cheap volume. As an exhaustive work on the same subject, though necessarily rather expensive, Nicholson's "Dictionary of Gardening" stands pre-eminent. Both these works are useful, far beyond the valuable help they give in the correct furnishing of the names of plants. Cassell's "Popular Educator" is also a valuable library in itself, dealing with an exceptionally large variety of subjects, and is consequently a most desirable work to possess. It gives a popular insight into a wide range of useful knowledge, and being handy for reference affords a ready means of consultation.

Plenty of literature is at hand dealing with practical gardening, and every detail of practice connected with it. Every phase of gardening is represented, and on the whole well. The works mentioned previously—namely, Johnson's and Nicholson's Dictionaries—contain abundance of cultural information. Thompson's "Gardener's Assistant" has for many years been a standard book on gardening knowledge, and still remains a most valuable work. The principal organs of plants are treated upon in a plain and useful manner; also the food of plants, and every detail in the management of a fully equipped gardening establishment. Such a book is a great help to obtaining an extensive knowledge of gardening, as in addition to the chapters on cultivation and management of crops in the open and under glass, full instructions are given on the use of every tool and instrument used in gardens. Another work less pretentious in character but yet very useful is "Cassell's Popular Gardening."

The preceding books being more of a general all-round character, there remains to be noticed now a few special works dealing exclusively with some particular subject. The first to be mentioned is a new and modern work entitled "The Fruit Grower's Guide," by John Wright. It is the latest and best work published on fruit growing, and aims at recording and illustrating in a manner never attempted before all the necessary details connected with growing fruit under every possible condition of culture. Prominent mention is made of this work not only for its excellence, but because the impetus given to fruit growing of late years renders it absolutely necessary that every ambitious gardener should make himself as thoroughly informed as possible on a subject that bids fair to take a more decided and important position than it has hitherto done.

As it would be impossible to mention all the works that deal specially with some particular phase of gardening, the following are indicated as desirable works to be in possession of—namely, "The English Flower Garden," by W. Robinson; "The Vegetable Garden," by A. Vilmorin; "Vines and Vine Culture," by A. F. Barron; "The Orchid Growers' Manual," by B. S. Williams. Before concluding this part of the subject it is necessary to point out, to some at least, that in addition to studying gardening with the aid of the most reliable standard works of information, regular attention ought to be given to the careful perusal of the contents of the horticultural Press, which, as a rule, gives a faithful reflex

of the methods of good gardening generally, and interesting records of results obtained. The Press, too, affords a ready means of consultation to perplexed inquirers who desire information for helping them out of any difficulty that may arise.

#### GENERAL ADVANTAGES.

That the general advantages of a wide and intelligent education in the principles of good gardening are manifold everyone will admit, whether they have had the foresight and opportunity or not of securing them. "Knowledge is power," and when combined with practical skill is doubly powerful. But theoretical knowledge alone is capable of conferring much benefit and pleasure upon the possessor. Take botany as an example. What endless vistas of knowledge are opened up by the simple study of the life history of a plant. Detail after detail, full of wonder and interest, crowds upon the observer as he carefully follows the process of development from the tiny seed to the perfect plant. Each process is a revelation, revealing more and more the beauties and wisdom of Nature. An interest in, and an incentive to, further study is

FIG. 7. MR. E. D. SMITH.

created. Armed with this power of seeing, step by step, the gardener feels better equipped for entering upon the more complex fields of thought and study which open up before him. It is the proper understanding of principles which gives the greatest satisfaction, and the more time given to the grasping of these the better will the subject in hand be understood as advancement is made both in theory and practical skill.

It may have seemed out of place to have recommended the perfecting of such simple subjects as spelling and writing, but then the advantages of such knowledge are seen when attempting to master higher things. Many a man is deterred from improving himself, even in the rudiments of his own profession, by the fact that this elementary part of his education is lamentably deficient, and he despairs of improving it, unfortunately seeing no advantage in doing so, consequently drifting into a kind of mental stagnation from which it is difficult to emerge.

The general advantages of pursuing steadily some course of study are not confined solely to the benefits accruing from the attainment of better technical and acquaintance with any particular subject, but also a wider effect is secured—namely, intellectual education, which gives fresh power to the understanding, drills the memory, exercises the observing powers, and generally improves the student almost unconsciously. It becomes much easier for the gardener to work, when he knows at least approximately the science of the operations he is called upon to perform. There is a world of meaning in some of the simplest details of gardening which would be all the better for being thoroughly studied and their purport made clear. There is supreme advantage in possessing as much thorough knowledge as possible, if for no other reason than that of taking away some of

the drudgery from commonplace work, replacing it with vivid interest in its possible results. The advantages of progressive education in gardening as outlined here are numerous. They will only be apparent, however, by steady perseverance in following up each point gained by attempting to conquer others, thus gaining knowledge on wide and liberal lines.

Bacon, the great philosopher, had a sincere regard for the advantages to be reaped from gardening, as he spoke of it as "the purest of human pleasures." He would, no doubt, have a similar regard for the advantages of education in the art of gardening (which in his time were considerably less than now), or he would not have given expression to the following pithy sentence, which it may be helpful to quote on the value of intellectual exercises: "Speaking makes a ready man; reading a full man; and writing an exact man."—E. D. SMITH.

[We deferred the publication of the concluding portion of this very good essay till a portrait of Mr. E. D. Smith could be obtained and prepared for insertion.]

ANGRÆCUM SESQUIPEDALE.

THOUGH known to botanists as long ago as 1822, this Orchid was not introduced to cultivation till some twenty-five or thirty years later. The credit of its introduction is due to the Rev. William Ellis, a distinguished traveller and historian of Madagascar, who, on his return from that island, brought with him living plants which he succeeded in flowering. In general appearance the plant somewhat resembles an *Aerides*, and if treated as such succeeds perfectly well. It attains a height of about 2 feet. The stem is erect, and is densely clothed with the fleshy distichous leaves, which are broad, strap-shaped, recurved, about 1 foot in length, and of a deep green colour. The stout peduncles are axillary, and bear from two to four flowers of great substance 6 inches or more across, pure ivory white and very fragrant. The spur is greenish in colour, about the thickness of a goose quill and of great length. The plant is well figured in the "Botanical Magazine," t. 5113.

Specimens are now flowering in the warm Orchid house at Kew, where the extraordinary appearance of the flowers excite the wonder of all beholders. In the same house are splendid specimens of *A. eburneum* and its variety *virens*, flowering profusely and diffusing a delightful fragrance.

#### HYBRID MASDEVALLIA.

The two best species of *Masdevallia* for garden purposes are undoubtedly *M. towarensis* and *M. Veitchi*. A hybrid between these was exhibited before the Orchid Committee of the Royal Horticultural Society at its last meeting, and was named *M. × McVitia*. It seems to possess a character intermediate between the parents. In general appearance it most closely resembles the seed parent *M. towarensis*, but the leaves are not quite so thick. The scape is about 9 inches long and very stout. The flowers are of a delicate rose colour. Though it is difficult to judge of the merits of a plant from a single flower, we believe that this hybrid will prove an acquisition. It was raised in the gardens of W. Thompson, Esq., Walton Grange, Stone, from seeds sown twelve or fourteen years ago, and has now flowered for the first time.—A. B.

#### SHOWING AND JUDGING HARDY FLOWERS.

I NEED hardly say that I have followed this discussion with the keenest interest, and hope that some practical action may result. Mr. Shanks' proposed wording for schedules on page 547 is, with your suggested amendments, the nearest to what we want of anything yet proposed. Is not a 1-inch tube too small? I do not think 2 inches would be found in practice too large for many things. At our small local show last year a spike of *Eryngium* was exhibited which would not have gone into a 1-inch tube. It was a fine specimen no doubt; but why exclude good specimens of this kind? Nor should I be averse to the inclusion of hardy annuals or even shrubs in some of the larger classes, say for thirty-six and upwards. Do I understand that the formation of a National Hardy Flower Society is contemplated? If so (and unless such is done I fear any model wording of the rules for showing hardy flowers will meet with little acceptance) let it be

clearly understood that it must be a truly "national" one, and, so far as possible, aiding the exhibitions of the Royal Horticultural Society. I am not a Fellow of the latter, but would rather add to its strength than weaken it. But the operations of the Society would require to be extended beyond this, and to include the United Kingdom, aiding say a certain number of selected shows in England, Scotland, and Ireland. Are the promoters prepared to face this?—S. ARNOTT.

THIS is an interesting subject, and one that has caused much trouble where the word herbaceous has been regarded as the important point to study. Judges interpret this word in so many ways. Used as I am to country exhibitions and judges, I find many of the latter are so little versed in hardy plants, good men though they be in other respects, that mistakes do often occur. Being secretary of a society, I found the difficulty described when one class was worded in the usual way of "twelve varieties hardy herbaceous flowers." We now word it thus, "eighteen varieties hardy cut flowers grown out of doors." The result is we get excellent stands of blooms, and seldom have any trouble with the exhibits. It is an advantage, I think, to word it thus, because we get so many flowers otherwise not admissible. For instance, shrubby *Spiræas*, *Philadelphus coronarius*, and *Magnolias* are quite as admissible as herbaceous *Phloxes* and such like. Not only is there a chance to show such worthy hardy flowers as those named, but we get much more variety in our exhibits.—S. P. H.

YES, the name hardy flowers will do; the next thing is, Will it stick? There is a story told of the late Mr. Jay, the noted dissenting minister of Bath. He had been listening with a friend to a sermon, and on leaving the place of worship his friend remarked it was a very powerful sermon. "Yes," said Mr. Jay, "very powerful, but will it stick? because it is not much use if it fails in this; there is no good in pouring water on a duck's back." Just so, and unless we can get the name to stick in the minds of schedule framers we shall still be "as you were." Supposing there be no explanatory note cutting out shrubs and annuals these could be shown, and *vice versa*.

The word "kinds" is more likely to be understood than "varieties," but I confess I think a larger class may be expected where this is not insisted on. At most exhibitions the chief anxiety of the officials is to cover the boards. Nothing looks much worse than 10 or 12 yards of empty boarding even if green-baized. Committees want exhibitors, especially if there be any entry fee attached, and while "varieties" differ so greatly in form and colour they may make a stand as attractive and interesting as if "kinds" had been the rule. Mr. Shanks himself seems rather to lean towards this; at any rate, he rather demurs to the Rev. F. Page Roberts's view (page 520) that "varieties" should not be allowed full points. My idea is rather to judge the stands as to other points first, and if otherwise equal to let "kinds" have the casting vote over "varieties."

Mr. Shanks and I are probably thinking of two classes of exhibitors as regards the tubes. He is fortunate, I fancy, in getting zinc tubes at the price he names on page 547; it might be borne by the generality of exhibitors. My experience leads me rather to suspect that many would sooner not go to even that expense. I arrive at this conclusion from the frequency with which I have been applied to in terms like this, when I have been urging friends to exhibit, "Oh, well! I don't mind showing if you will lend me a stand and tubes," and to this day I am still minus one of these loans, never returned. I, however, had cottagers chiefly in my mind. Such rules as to size would be general, and would touch the cottager seriously. My experience is that it is very difficult to get up any enthusiasm as to exhibiting in some persons, who nevertheless grow flowers most successfully. There are many persons both amongst the better class amateurs and cottagers who want everything done for them. The remarks on this subject already show what diversity of opinion there would be on the size of the tube, "A. D." suggesting 2 inches diameter, whilst Mr. Shanks is content with those 1 inch in diameter. So far as my experience goes these rules are carried out with a certain amount of latitude, and if the tubes, or even the box or stand, is not quite correct as to inches, there is rarely a disqualification on this account; much in the same way as to the times of receiving exhibits and the readiness for the judges.—Y. B. A. Z.

[If making a great "show" is to be the chief object, then the word "varieties," twelve or twenty-four, or whatever the number may be, will tend to that result; but several distinct varieties, say of Pinks or Carnations, may then be included in a stand. If kinds are stipulated for there would be greater diversity, and the displays would be more instructive. It would be perfectly easy if desired to stipulate that, say, two (or more) distinct varieties are admissible

in a stand of twelve bunches, with a proportionately greater number in larger classes. The great desideratum is to have the terms so clear that all exhibitors may know exactly what they must do to be within them. It ought to be as easy to avoid confusion in staging flowers as fruit. Fruit classes are made clear by being based on the word "kinds," with provisos specifying the number of varieties. It is seldom that confusion arises in either staging or judging in these classes, but uncertainty, not to say bewilderment, is much too common, both on the part of exhibitors and adjudicators, in connection with classes devoted to hardy flowers on account of the ambiguity or laxity of the terms employed in schedules. For providing imposing displays the method of allotting space to trade growers for them to occupy in the manner they deem the most effective seldom fails. Under such conditions no doubt the finest collections of hardy cut flowers the world has seen have been displayed at exhibitions in this country. We are not cognisant of any widespread demand for a special society, as alluded to by Mr. Arnott.]

### CANKER ON FRUIT TREES.

I AM much obliged to Mr. Tonks for his lucid article on page 15, and wish to tell him that I intend, on a soil similar to that of which the analysis was given, to try the effect of special applications of potash, lime, phosphoric acid, and sulphate of iron on considerable breadths of ground. I hope to send the result to the *Journal*. In reply to "B. D. K." (page 27), I can say that I have tried for several years the application of neat petroleum (*i.e.*, the ordinary crystal oil) well worked into the cankered places with a paint brush every spring. The wounds have not healed, but seem rather better than when it was first applied. Still it is evidently not a successful remedy by itself. It is, of course, a powerful insecticide, and after a trial of it it is difficult to see how the insect theory can be maintained as a cause of canker, for I cannot conceive of any insects frequenting the places for months after. It was put on in dry weather, and the dry bark would soak it up and hold the oil for a long time. It does not appear to have injured the trees in the slightest, though it has in many cases run down the bark below the wounds.

If the fungus theory be correct, the wash should be a fungicide, not an insecticide, and similar treatment to that recommended by Mr. Abbey for Apple scab, applied at the right time should be sufficient. If the cure of canker depends upon the destruction of every cankered Apple tree in the locality that would furnish a supply of spores, it may be regarded as a hopeless case. My own opinion is that the root of the matter lies in the nutrition of the tree—*i.e.*, at the roots, and that a tree, like a human being, will not take disease if in a thoroughly healthy condition, and that this may be arrived at by supplying all the constituents necessary to keep the tree in health, and I think that this would really be the treatment of "the experienced practitioner," rather than of "the quack." Possibly the removal of poisonous elements may be necessary, but the experience of Mr. Tonks proves that canker is curable, at any rate in his soil, by the application of what the tree needs to build up a healthy growth.

Some sorts of trees appear to have a better constitution than others, or perhaps greater foraging powers, and a greater capacity to appropriate from the soil what is necessary for its existence, when it exists in limited quantity. Stocks probably influence in a similar way, and may account for variations in trees which are grafted with the same variety. On our soil it is not a question of which are the best sorts, but which are the healthiest sorts, then which are the best of these. Cobham for instance—that appears to do so well with many of your correspondents, and which I obtained from two reliable sources—cankers to death here, and I am just grubbing a number of trees which have been planted five years. It is also the same with a great many other sorts. On marking for destruction two trial trees of Gloria Mundi, which have also cankered to death, the Latin proverb, *Sic transit gloria mundi*, appeared most appropriate. Irish Peach is a sort which is very free from canker, but unfortunately grows and crops here very badly, and the fruit produced is almost worthless.

On reading Mr. Abbey's interesting article (page 27), I notice that he has misunderstood the purport of a sentence in my note. The reason I mentioned that Plums do well, while Apples and Pears cankered and Cherries gummed, was not because I was surprised at it, or expected them to be unhealthy, but to furnish the utmost data as to the soil in question; for Mr. Abbey is doubtless aware that, from the healthy growth of certain plants and fruits, the presence of certain soil constituents may be inferred.—WALTER KRUSE.

[We have other letters on this subject, but it will be best to defer their publication till Mr. Abbey's comprehensive notes are inserted.]

### A REVIEW OF SOILS.

MR. KRUSE states: "As the same varieties of Pears and Apples canker on one soil and do not do so on another, it seems a correct deduction that when they canker there is either something injurious in the soil or something lacking which they need." Then follows an analysis of the soil in which Pear and Apple trees canker by the late Dr. Voelcker (*Journal of Horticulture*, December 29th, 1892, page 564). Mr. Kruse proceeds to draw conclusions from the analysis: "It will be noticed that there is a large proportion of oxide of iron, as where there is more

iron (how is this known?) still in the soil in the same locality, Apples canker still more, and as it has been mentioned by some of your correspondents that Apples canker where there is much iron in the soil or subsoil, it would appear that excess of this is the cause of the canker."

I have shown in a previous article that canker is caused by a fungus, *Nectria ditissima*, and it goes without saying that iron will not produce any form of vegetable life, though it may and does form a fitting nidus or soil for the germination of the spores of fungi and the development of the fungal plants, also the perfection of their "fruits." But as there may be cankerous affections without fungal growths we may approach the subject broached by Mr. Kruse without preconception of ideas and conclusions founded on prejudice.

Iron as a cause of canker in Apple and Pear trees. The soil (see analysis on the page above cited) does not contain "a large proportion of oxide of iron," that is 3.38 per cent. as compared with soils that produce the finest Apples. Mr. Kruse, however, does not confine his remarks to the analysis as an Apple soil, but considers it "a good soil for fruit growing," and as Kent is famed for its fruit, subjoined is an analysis of a soil found suitable for fruit production or Hops near Sittingbourne;—

*Organic matter and loss on heating	...	...	5.07
Oxide of iron	...	...	3.63
Alumina	...	...	1.63
Carbonate of lime	...	...	1.48
Sulphate of lime	...	...	0.34
Magnesia	...	...	0.42
Potash	...	...	0.30
Soda	...	...	0.01
Phosphoric acid	...	...	0.10
Insoluble silicates and sand	...	...	84.14
			100.00
*Containing nitrogen	...	...	0.19
Equal to ammonia...	...	...	0.23

—(*Fream's "Elements of Agriculture,"* page 21.)

The "Leeds" soil analysis shows a higher per-centage of essential fruit-food—potash, 0.21, phosphoric acid, 0.14—than the Sittingbourne; also more alumina (2.72), carbonate of lime (2.43), magnesia (0.15), and soda (0.06); but less iron (0.26), sulphate of lime (0.08), insoluble siliceous matter (1.27), organic matter, the store from which ammonia—nitrogen is manufactured (1.43). Mr. Kruse will note the fact that Sittingbourne is the home of the cultivated Cherries in this country, and have a world-wide celebrity, yet they gum there, and Apple and Pear trees canker. Nevertheless, Cherry trees are less subject to gum at Sittingbourne than in many other soils, because they are aided against it by the larger amount of siliceous matter and iron available for the strengthening of their epidermal tissues, whilst these are kept elastic by the free manufacture of ammonia (0.02 more in the Sittingbourne than in the Leeds analysis), = nitrogen (also 0.02 better in the Sittingbourne than the Leeds analysis, a mere matter of equivalents).

If Mr. Kruse's deductions are correct, Apple and Pear trees ought to canker more at Sittingbourne than at Leeds. There is more iron and siliceous matter; in the Leeds soil the iron is sealed up in the alumina, and the two together eat up the ammonia, that is, there is not enough ammonia manufactured to ammoniate the iron and render it available as plant food. Why? 1, The organic matter is low, more "muck" is wanted, twenty-one tons of farmyard manure every third year at least, per acre, or its equivalent in "artificial," which I will allude to later. 2, The Leeds soil is retentive, far more so than the Sittingbourne, by reason of the alumina; therefore, the air and rain cannot enter or pass through such soil and make its constituents as quickly available as in the other soil, which, however, has greater powers of manufacture chemically in the carbonate of lime, but they cannot be exerted because the mechanical nature of the soil prevents it. That is the reason the Sittingbourne soil, chemically poorer, is better for fruit production and Hops than the richer Leeds staple. The carbonate of lime contributes to make the soil mechanically as well as chemically unable to manufacture plant food sufficiently fast for the requirements of the trees, and, though richer in constituents, it is poorer actually as regards output in fruit in the most saleable form than the Sittingbourne, in which the supplies are less but more available.

In the Leeds soil the stores of food are locked up perhaps in a "pan," in that at Sittingbourne there are "no bars" to hinder the trees from abstracting the amount of food essential to their health and fruitfulness, because there is no pan such as must obtain in the Leeds soil from its composition—its calcareous nature. The carbonate of lime must dissolve and descend, and it will form a lime pan somewhere, generally at a moderate depth from the surface, too near in many cases for the long continuance in health of Cherry, Apple, and Pear trees—the former gumming and the latter cankering. The lime and the siliceous matter combine to form a concrete—mortar like, and the iron of the soil is washed into this pan, cakes and forms what is called an iron subsoil, and with the alumina holds ammonia as the smith does iron in a vice, so that it is practically useless to the trees (Cherry, Apple, and Pear), and the iron corrodes their roots and the tops canker. Plums succeed—no gum. The soil suits that fruit—the iron in a pan is held there to its especial benefit. Green Gage requires 6.04 per cent. in the whole fruit, and 7.45 per cent. in its skin, but the Cherry only needs 3.74 per

cent., and the Apple 2.65 per cent., whilst the Pear is content with 1.96 per cent. of iron in its fruit.

We, therefore, understand why and how a rusty sword (Leeds soil) will only grow Plums, Gooseberries, Black and Red Currants profitably, and the Sittingbourne soil—the bright, sharp, tempered iron—produce Apples, Cherries, Currants, Gooseberries, Pears, and Plums with Hops into the bargain. Plums, Gooseberries, and Currants are shallow rooters, therefore they will thrive on calcareous, aluminous, iron soil, where the pan is only at a moderate depth from the surface; also better than Apples, Cherries, and Pears where there is a plough pan, or there is lesser depth of ameliorated soil. Consequently Mr. Kruse must look to the mechanical condition of the soil as well as to its chemical constituents.

I would observe further that the best Apple soils of this country are “red”—due to the presence of a considerable amount or percentage of oxide of iron. The old red sandstone soils are the best for the production of heavy rich fruit, Apples making the best cider and Pears giving the finest perry, as in Herefordshire and elsewhere. (See a geological map of Great Britain). Red soils that have resulted from the commingling of old red sandstones and marls, carboniferous shales, and limestone, fragments of igneous rocks, and glacial detritus, as in the central valley of Scotland, are Apple soils. The red soils of the new red sandstone and so by reason of the iron they contain, and being friable and incumbent on a marly sandstone, produce healthy Apple trees and abundant crops. This is seen on the trias in Devonshire, Somersetshire, Gloucestershire, Worcestershire, and Warwickshire; in Staffordshire, Cheshire, Lancashire, in the Trent Valley in Nottinghamshire, with a strip only in Yorkshire, and patch in the Tees Valley.

Apples are addicted to these red soils, Devon and Gloucester cider rivals that of Hereford. Irony Sussex soils grow more solid and richer Apples than less ferrous Kent, and make cider of superior quality; even the Hastings sands give Apples more colour than the richer soil of the Medway Valley imparts. The vales of Berkeley, Evesham, and Gloucester are a rich brown soil of the lias formation, and are renowned for Apples, fruit, and cheese, the middle lias marlstone (a mixture of clay and sand with a considerable quantity of limestone) provides the rich soil that Apple trees thrive in in Somerset. Those are irony soils, so is Rutland (red land), famous for its healthy trees. Sussex, the iron land of the south, may be poisoned with iron silicates, barren where there is only a few inches of soil over an impenetrable pan, or where a siliceous soil is mingled with iron nodules grow Heath and Fir, but where the lower greensand fringes the Weald clay on the north, west, and south, and is calcareous and dry, it forms one of the most fertile soils—the series known as the Hythe beds—and will grow anything, fruit and Hops. The large, bright, matchless Kent Apples are due to Kentish rag (beds of limestone), “hassock” (soft sandstone), and an admixture of brick-earth—Nature’s blending, not too much nor too little iron, but the nearer 4 per cent. than under 3.50 per cent. the brighter, heavier, and richer the Apples, always provided the drainage is thorough and the soil a good depth. Cherries grow free from gum in the Woburn sands, and send their roots down no one knows where; but in the extraordinary productive vegetable farms of Sandy (Bedfordshire) Apple trees are “eaten up” by canker.

Alluvium and drift are heterogeneous accumulations of mineral matter—a little of almost every substance, and good or bad according to those components, the depth of the ameliorated soil, its staple and the subsoil, with freedom from stagnant water. Alluvial soils—the “haughs” of Northumberland, banks or lands near the Ouse, Derwent, Trent, and Humber, draining the great Vale of York and Trent valley; the Thames, Avon (Bristol), Wye (Monmouth), Usk and Severn valleys—are irony, good Apple soils above the line of floods, and free from stagnant water. At Tadcaster, on the river Wharfe, above or below that place are some orchards on alluvial or warp soil, sandy or deep, that produce better Apples than good loam on magnesian limestone because more irony, and that iron ammoniated through the greater amount of organic matter manufacturing ammonia. The alluvial deposits of the Derwent near Malton, resting on kimmeridge clay, the subsoil clay, but not waterlogged, produce abundant crop of Apples—Keswick Codlin, Ecklinville Seedling, Adam’s Pearmain, Large Cockpit, Ribston Pippin (where the soil is well drained), Baumann’s Red Reinette, Golden Reinette, and Golden Russet. Alluvial soils are rich in iron and organic matter, but very poor in lime, yet they seem to get some—that is, in the case just mentioned by the Ouse from the oolitic and chalk hill; and warp lands receive enough in the water to make the grass “jump,” and lands not actually flooded may in flood time obtain the lime that causes the Apple trees grown thereon to produce 40 pecks per specimen in full bearing.—G. ABBEY.

(To be continued.)

### ANGIOPTERIS EVECTA.

To those about erecting a fernery where roof room is no object this handsome greenhouse Fern forms one of the noblest one could possibly find, and I know of no Fern which produces such a tropical appearance. To see it grown in tubs is no criterion of the proportions it assumes when planted out, as the fronds in the first case are stunted and often of a sickly green colour, whilst in the latter they will with proper attention reach a length of from 16 to 20 feet and carry a deep green colour.

To anyone not acquainted with it I would advise planting in a mixture of good lumpy loam and peat, adding coarse sand and broken sandstone, and in close proximity to a pond, where the roots will soon

find their way and simply revel in the position assigned to them. Another important point is that wherever it is planted the rockwork should be built in such a position as to allow copious supplies of water to be given to those roots which do not reach the pond. If this is borne in mind and the Fern receives frequent syringings there is little fear of thrips—the only enemy to which this Fern is subject—making their appearance.

Anyone having plants languishing in a sickly condition in tubs would greatly enhance their beauty by planting them in the rockery, where with moderate roof room they will steadily improve, for it takes many years for it to get thoroughly established and assume such gigantic proportions as I have mentioned.—R. P. R.

MADAME FALCOT.

I QUITE agree with “J. C.’s” remarks (page 554) as to the great beauty and usefulness of this charming variety. It was quite an oversight on my part not to have included it in my list; but among so many good things it is not always easy to remember all the “gems” at one time. Madame Falcot is one of those delightful Roses which seem to awaken instinctive admiration on account of the soft yellow colour of its finely formed buds.—H. DUNKIN.

### COMMENTS.

I HAVE read “W. R. Raillem’s” letter in the Journal of 5th January (page 5) with deep interest, and will venture to make a few remarks upon it. Having been unable to attend the annual general meeting of the N.R.S. I cannot comment on it much, nor do I think it necessary for such a novice as myself (as compared to “W. R. R.”) to do so. I only hope his remarks will be a warning to us all whenever provincial shows of the N.R.S. are held in our localities. The next provincial will be in my own district, and I hope there will be plenty of room for all exhibits including “W. R. R.’s.” We shall be sorry to see or hear of such an enthusiastic rosarian as he is “dropping out” on the plea of “old age” or single-handedness. I am pleased to read “that the financial statement of the N.R.S. showed a balance on the right side at any rate, although perhaps not a very large one.” Let us hope to see that balance considerably increased and in a “flourishing condition” when the number of northern exhibitors and those from “late land” increase to such an extent that they will compose a good 50 per cent. of the members of the N.R.S. “W. R. R.’s” suggestion about punctuality in paying subscriptions is a very good one, and if such a course could be adopted by members of many societies it would be a great saving of labour to treasurers and others who are good enough to undertake the unenviable duty of collecting subscriptions.

Let us hope to see a provincial exhibition in East Anglia before many seasons have passed by, and a financial statement there very flourishing. We who live in the more northern and midland counties know what agricultural depression is, and although we cannot afford to contribute our mites indiscreetly, at the same time we shall give the provincial Show a welcome, and do our little best to make it a success, trusting we shall have all possible support and assistance from Rose exhibitors and others, and then we shall only need that most important factor, fine weather, to enable us to realise our hoped for result. I am sure “W. R. R.” will agree that we want more Rose growers from the midland and north to take an interest in and belong to our National Society, but to enable us to enlist many enthusiastic exhibiting members we must have provincial shows held in our midst from time to time, and this is not all. The N.R.S. would do well to hold the metropolitan Exhibition upon some date suitable, as far as possible, to all Rose districts and growers of all families of Roses. It will never be a truly popular and united National Society so long as the greatest exhibition is held for the benefit of any one district, be it north or south, or any one family of Roses, though it is very difficult to fix upon such a date owing to the variable seasons we experience from year to year.

I was strongly in favour of the resolution proposed by Mr. Pemberton at the general meeting above mentioned (I refer to the resolution, “That the metropolitan Exhibition be held on the Saturday nearest 6th July”), not because I thought “my Roses would be at anything like their best” on that date in an average season, for I fear that would only be the case once in every six or seven years, and my maidens would not be in bloom even then. I may be wrong, but I do not think Roses, H.P.’s, at any rate, in the south, and on early land, would be much, if at all, past their prime six seasons out of seven on July 6th. Small growers ought to have all due consideration, and no doubt there are many of them amongst members of the N.R.S.; many, perhaps, who only grow cut-backs, too, and who have not the maiden plants that others have to prolong the time of blooming with. All classes of exhibiting members deserve consideration, large growers included, for they cannot grow plants by the thousand and produce first-rate blooms without a good deal of expense in cultivating and exhibiting the Rose. Northern growers, and growers on late land, also deserve a share of consideration, for it is evident that they cannot exhibit from their gardens with any

hopes of success, even if they can exhibit at all, in their respective divisions—i.e., according to the number of plants of exhibition varieties they grow, until enough plants are producing something like a representative number of flowers in proportion to the number of plants grown.

My personal experience is that we, even, who live thus far north have several disadvantages (as compared with growers nearer Sydenham) to contend with. Firstly, as members; secondly, as growers and exhibitors. As members we have to sacrifice more time and money to enable us to attend a general meeting of the N.R.S., and so on. As growers and exhibitors we have probably more severe winters and (perhaps what is more important) more severe springs, for a severe spring with cold cutting winds will often ruin our first crop of Roses. We also, as exhibitors, have a longer distance to go to Sydenham, whether we have Roses to exhibit, or whether, owing to the earliness of the metropolitan fixture, we being unable to exhibit, wish to see the exhibits of "growers in the south and on early land," or, as a working man has expressed himself, "growers nearer the sun."

I must now conclude, hoping at some future time to see northern-exhibiting growers forming at least 50 per cent. of the number of members of the N.R.S.; but in the meanwhile they must trust somewhat to the generosity and foresight of the majority for a solution of one or two problems, which if solved impartially and unselfishly will, I am sure, be forwarding the future interests of the Society, by gaining for it more northern support and more enthusiastic northern-exhibiting members. A National Rose Society deserves the support of the whole nation, and I am sure it needs it to make it a prosperous and united Society; therefore let us all be enthusiastic, generous, and united in our endeavours to support a Society which encourages the cultivation of our national flower.—HENRY V. MACHIN, *Gateford Hill, Worksop.*

**THE WEATHER IN LONDON.**—Several changes in the weather have taken place since last week. Sunday opened dry, frosty, and very cold, with occasional slight falls of snow during the day. A severe frost occurred at night, and on Monday morning a little more snow fell, but eventually it rained. Tuesday was frosty in the morning, but snow fell before mid-day and continued until night. Wednesday opened wet, and at the time of going to press it is raining.

**— WEATHER IN THE NORTH.**—The past week has been generally bright and cold and frosty throughout; 15° frost on the morning of the 12th. On the morning of Saturday a slight shower of snow fell. During the evening of Sunday a thaw set in, but it seems as if again setting towards frost.—B. D., *S. Perthshire.*

**— THE GARDENERS' ORPHAN FUND.**—The annual general meeting of the subscribers to this Fund will be held at the Cannon Street Hotel on Friday, February 3rd for the purpose of receiving the report of the Committee and accounts of the Fund for 1892, electing officers for the ensuing year, and for the election of eight children to the benefits of the Fund. The chair will be taken at two o'clock precisely, and the ballot will close at four o'clock. The voting papers have all been issued. Any subscriber not having received one is requested to intimate the same to Mr. A. F. Barron, Hon. Secretary, Royal Horticultural Society's Gardens, Chiswick.

**— VEITCH MEMORIAL PRIZES AND MEDALS FOR 1893.**—A meeting of the Veitch Memorial Trustees was held on January 17th, Dr. Hogg in the chair. It was decided to offer the following prizes and medals in 1893. Royal Horticultural Society, Temple Show, a medal for the best six hardwooded plants in flower. Manchester, medals for the best hybrid Orchid in flower in commerce and for the best hybrid Orchid in flower not in commerce. Ghent International Exhibition, medal for the best hybrid in the Show. Clay Cross Show, one prize and one medal, subject not determined. Royal Horticultural Society's Fruit Show, Agricultural Hall, one medal and one prize. A prize of £5 is attached to each medal.

**— OUTDOOR MUSHROOMS IN THE NORTH.**—A Yorkshire correspondent writes:—We are doing well with Mushrooms on open-air ridges. During the past few weeks I have gathered over 700 lbs., although we have had three weeks of very severe frost. We gathered over half a cwt. this afternoon (January 11th), which proves that the advice given in "Mushrooms for the Million" is not very wrong.

**— ROYAL HORTICULTURAL SOCIETY.**—According to the terms of the Charter one-fifth of the members of the Council retire yearly. This year the names of members vacating are Baron Schröder, Rev. W. Wilks, and Mr. Sherwood. The names of Fellows recommended by the Council to fill the vacancies are Sir John Llewellyn, Bart., the Hon. Walter Rothschild, and Mr. J. T. Bennett-Poë. The officers that will be recommended by the Council to the Fellows at the annual meeting on February 14th are Sir Trevor Lawrence, Bart., M.P., as President; Mr. Philip Crowley, F.L.S., Treasurer; Rev. W. Wilks, M.A., Secretary; and Messrs. Harry Turner, Henry Williams, and A. H. Pearson, Auditors. Mr. Wilks, who has worked laboriously for the Society during the past five years gratuitously, asked to retire in order that he could accept an advantageous offer which he did not feel justified in refusing. As the Council have the power to make the Secretaryship a salaried office, Mr. Wilks has consented to decline the offer above referred to, and to continue to serve the Society as its Secretary. His vacation from the Council is in accordance with the terms of the Charter, as no salaried official is eligible for a seat. We venture to think, as we sincerely hope, that Mr. Wilks will be unanimously elected to the important position for which he is recommended, as a more zealous, active, and able official it would be difficult to conceive.

**— THE POTATO DISEASE.**—According to Dr. J. Böhm, the statement that *Phytophthora infestans*, the fungus which causes the Potato disease, hibernates in the tubers, is incorrect, nothing whatever being known about its mode of hibernation. He further states that the infection of the Potatoes never takes place in the soil through the uninjured skin, but is always brought about through injury to the tubers by insects or snails.

**— POISONOUS EFFECTS OF THE NECTAR OF THE JUDAS TREE.**—An American divine, who shall for the present be nameless, in a book of illustrations drawn from Nature (or presumed to be) states that the nectar of the Judas Tree (*Cercis siliquastrum*) is fatal to most insects, but yet they persist in imbibing it, so that during the time of flowering, bees, flies, and various species may be seen lying round a tree by scores. Perhaps some gardener who has this tree under observation can tell me whether the statement has any foundation in fact.—J. R. S. CLIFFORD.

**— MANURE AND TEMPERATURE.**—For a number of years I have been trying experiments with chemical manures, and have had both success and failures with the same manures on the same kinds of plants all grown in the same kind of soil. Plants growing in a low temperature bear no comparison with those that have more heat. These latter are wholly satisfactory, the others somewhat disappointing. The query is, Do plants grown in the open require more nitrates or other ingredients to bring them to a proportionate perfection with those grown under glass? It is quite evident that heat favours the growth of artificial manure-fed plants more than those in a colder soil or atmosphere.—T. N. B.

**— TULIPS IN POTS.**—Few things are more useful and showy for decorative purposes during the present and two succeeding months than these easily managed bulbs. They bear sharp forcing wonderfully well if properly prepared for the ordeal by allowing them to make fully an inch of growth above the soil before they are removed from the plunging material. Many bulbs are annually spoilt by not paying due attention to this important detail. Unless root action is well advanced before the bulbs are placed into heat, stunted growth and small flowers are the result. We have 5-inch pots containing five bulbs each, which have been used for room decoration during the last sixteen days. Few flowering plants at this season will keep fresh under similar conditions for so long a time.—H. D.

**— BIRDS.**—Although I mention at times the destructive nature of some birds (wish I could free the blue tits from the list), it does not follow that I kill them, or what I think worse, trap them to live a miserable and brief life after. On the contrary, I have hitherto protected them, and have had experience of some remarkable incidents and anecdotes with birds, as well as other animals, worth recording. One I took a great interest in was a robin, which followed me throughout the garden, and came to me when I called on it. I knew its chirp when hungry, and a worm or two satisfied it. Then I would shake the bushes for it to pick up the various insects, and at this it never seemed satisfied. At dusk, if it did not come of its own accord, I called it to sing me its evening song. It came, sat on a branch close to me, and poured out its lays for about ten minutes, then would disappear for the night.—W. T., *Blantyre.*

— **ELTHAM ROSE AND HORTICULTURAL SHOW.**—We are requested to announce that the date of the above Show is fixed for June 29th.

— **A WHITE ANTHURIUM.**—Says an American contemporary:—"A white variety of *Anthurium Andreanum* has originated with a Belgian amateur; it has received the somewhat unwieldy title of *A. Andreanum Wambekeanum*. The plant preserves all the characteristics of the ordinary form, excepting the colour of the spathe."

— **DEATH OF MRS. AYRES.**—We are requested to announce the death of Mrs. Ayres, widow of the late Mr. William Port Ayres, who died in 1875. Mrs. Ayres, we are told, was "every inch a gardener," and was accustomed to write articles for the gardening press when her husband was ill. Mrs. Ayres died at Acton, aged seventy-five, and was interred there last week.

— **MR. W. K. WOODCOCK.**—After a series of very successful lectures in Norfolk Mr. Woodcock has been appointed Horticultural Instructor by the Norfolk County Council, and after this season will be fully employed in East Anglia. Mr. Woodcock is a sound and effective teacher both on the platform and the land. His business at Syston will be continued as usual.

— **TORQUAY DISTRICT GARDENERS' ASSOCIATION.**—The first annual dinner of the above was held at the Exeter Hotel, Torquay, on Wednesday, January 11th. Over seventy members attended. Mr. W. Ainslie occupied the chair, and Mr. W. B. Smale was Vice-Chairman. The Society was stated to be in a financially good condition, and increasing in membership. A reference library will shortly be formed, valuable works (including two bound volumes of the *Journal of Horticulture*) having been promised by the President (Mr. W. Lavers), Mr. Ainslie, and others.

— **WINTER TOMATOES.**—Last autumn the Fruit Committee of the Royal Horticultural Society gave a certificate of merit to a Tomato as a winter cropper, although when exhibited several times last winter it was not thought good enough. How the Committee came to its final conclusion I do not know, but as one much interested in the getting of winter Tomatoes I should like to ask that samples of fruit of this or indeed of any other presumably winter variety should be shown at some of the remaining winter meetings at the Drill Hall. We should be all delighted to meet with a Tomato that would give us such fruits in winter and as freely as Conference, Ham Green Favourite, or Challenger does in the summer and autumn.—**TOMATO.**

— **GESNERA BLOOMS FALLING.**—Will some reader of the *Journal of Horticulture* kindly advise me as to the growth of Gesneras? For fourteen or fifteen years I have grown these plants successfully, but this year, although I have given them the same treatment and the plants are very strong and healthy, and have thrown up some good spikes, every bloom falls off just when about to open. I have them 2 feet through in 7-inch pots, with two parts loam, one of peat, one of leaf mould, and a little silver sand. Some of the plants are near the glass and others are not; some are in the warmer part of the stove and others in the cool position. I have tried keeping them rather dry, and also a little moist, but with the same result, every bloom drops off. The following are the varieties I possess:—cinnabarina, exoniensis, refulgens, splendens, and zebrina.—**J. D.**

— **IMPORTED AZALEAS.**—I was very much interested in Mr. J. B. Riding's timely remarks on this subject in the *Journal*, December 29th (page 569). It is a fact that many gardeners are prejudiced against imported *Azalea indica*. For my part I prefer them to many home-grown plants I have seen; they are a better shape, and better furnished with flower buds. As Mr. Riding refers to the plants as they are imported, perhaps you will allow me space for a few remarks on plants that are purchased in pots. I have known many instances where the pots have not been properly drained, one crock only being placed in the bottom. It is needless to say that this is far from being sufficient. The compost also has not been rammed around the ball, so that there were hollow spaces between the ball and the sides of the pot. Plants potted in such a careless manner cannot be expected to thrive. Purchasers would do well to examine their plants as soon as they receive them, and if needed repot, provided the flower buds are not too far advanced; if so defer the operation until the plants have done flowering. Another great mistake is keeping the plants in too warm a temperature before they get established in the pots.—**C. RUSSELL.**

— **WEALTHY APPLE.**—A correspondent ("F. H.") asks if any of our readers can give him the name of the raiser of the above Apple.

— **GARDENING APPOINTMENT.**—Mr. D. Brough, late gardener to Lord St. Oswald, at Nostell Priory, Yorkshire, has been appointed gardener to Sir Archibald Edmondstone, Bart, Duntreath Castle, Strathblane, Stirlingshire.

— **SHROPSHIRE HORTICULTURAL SOCIETY.**—We are informed that the enterprising officials of this very successful Society have just purchased for £3150 some fields adjacent to the show ground, and hope eventually to continue the promenade to the same, and plant trees and other things.

— **HORTICULTURAL INSTRUCTION.**—Mr. G. Garner, Amberwood, Christchurch, Hants, has been appointed by the Poole Technical Instruction Committee to deliver a course of lectures on horticulture. The first was given at Parkstone on January 10th on the Chrysanthemum, and was most instructive.—**K.**

— **HORTICULTURAL SCHOLARSHIPS.**—Horticultural scholarships are now becoming numerous. In addition to those offered by the Worshipful Company of Gardeners and by Sir Trevor Lawrence, Bart., President of the Royal Horticultural Society, we are informed that Baron Schröder has instituted a similar scholarship of £26 annual value for two years.

— **THE LATE SIR JAMES WM. MACKEY'S BUSINESS.**—We are requested to state that the family of the late Sir James Wm. Mackey of Dublin, in accordance with his desire, will continue the seed business, founded in 1777, under the management of Mr. A. O. Watkins, who so ably managed for Sir James Wm. Mackey during his illness for the past two years.

— **ANCIENT SOCIETY OF YORK FLORISTS.**—The annual meeting of the Ancient Society of York Florists was held last week at York. Mr. R. McIntosh presided, and there was a very good attendance of members. Mr. J. Lazenby, the Secretary, read the annual report, which stated that the financial position of the Society was still satisfactory. The subscribing members this year reached 531, which was the highest number yet attained, and an increase on last year of forty-five, and more than thirty names had been submitted since the books were made up. The gross income was £627, and the expenditure £450 10s. 1d., the balance credit being £176 10s.

— **INCORRECT ADDRESS.**—Mr. A. Dean writes from Richmond Road, Kingston-on-Thames: "Kindly permit me to ask you to mention that the publication in the list of members of the Fruit Committee in your columns, copied, of course, from the official list, of my address at Bedfont, Feltham, is incorrect, as I have been residing here for the past eighteen months; and so well is that fact known at 117, Victoria Street, that whilst the error remains uncorrected, yet all their communications are addressed to me here. It is presumably a piece of official oddity." [The address was taken from the list supplied by the Royal Horticultural Society.]

— **THE TITS AND THEIR HABITS.**—I did not speak of the smaller tit in my note on this subject (page 18), as I had nothing but negative evidence to offer, and fancied there was enough of this already. I have never heard of nor seen this bird killing bees in this locality, nor have I seen it destroying fruit buds in my garden. I am making inquiry as to its habits in other gardens, and may return to the subject again. Mr. Hiam, in his interesting note (page 39), appears to have forgotten that the propensities of the large tit have been discussed as well as those of the small one. On page 547 of last volume he himself speaks of *Parus major* and says, *inter alia*, "*Parus major*, commonly known locally as 'Tom Collier,' is also particularly fond of bees, but I have never been able to discover one killing my bees." "A Lanarkshire Bee-keeper" also described *P. major* as killing his bees, and I see Mr. Hiam alludes to his statement that the birds tapped on the hive. I, therefore, think that my short note on the large tit killing my bees was not outside the limits of the discussion. Since I saw Mr. Hiam's last note I have seen the large tit pecking vigorously at a piece of suet, placed for the benefit of the birds this severe weather. I cannot refrain from expressing the conviction that most birds, while doing a certain amount of damage in gardens, are beneficial in many other ways. Even the blackbird, with all his propensities for levying toll from the Peas and Gooseberries, does some service here by killing great numbers of the large grey snail—*Helix aspersa*—which is very numerous here.—**S. ARNOTT, Dumfries.**

— **RAINFALL IN SHROPSHIRE.**—Mr. C. A. Pearce, Oteley Gardens, Ellesmere, Salop, sends us a tabulated account of the rainfall there in 1892. "We note that 27.48 inches of rain fell on 193 days. Mr. Pearce remarks that although there has been three days more than in 1891, the rainfall has been 6.16 (or something like 750 tons) less per acre. The total weight of rain for the year at a rough calculation is something over 2780 tons per acre. We have experienced a very late, sunless, cold season, which invariably means insipid, flavourless fruit, light crops, light corn, and poor washy herbage."

— **A DELAY OF EXHIBITOR'S PRODUCE.**—A case of some importance to exhibitors was settled in the Leicester County Court last week, when George William Hunt, gardener, South Knighton Road, Leicester, sued the Midland Railway Company for £25 for delay in the delivery of some vegetables at a Crystal Palace show last year. The case being stated, the Judge pointed out that in awarding any damages they must consider how much money had been really lost in not being able to exhibit and secure the customary prizes, the jury gave a verdict for the plaintiff with £10 10s. damages with costs.

— **LECTURES IN HORTICULTURE.**—Mr. T. Emmott desires us to state that under the direction of the East Riding County Council twelve lectures are being given in Howden by Dr. James Clarke, M.A., of the Yorkshire College, Leeds. On Monday last, at the introductory lecture, 110 persons were present, and the lecture was listened to with great attention. Dr. Clarke is an able teacher and avoids the use of technical terms except when it is impossible to do so. He makes great use of the blackboard to illustrate what he says. Howden is a noted gardening district, and possesses a very good local horticultural show.

— **THE POOR PRINTER.**—Thus does a correspondent introduce the announcement of a discovery. Only a lady would be so observant and sympathetic. We transcribe verbatim. "Has your printer got a cold in his 'dose,' or is Williams' Giant Logpod Bean in the advertisement facing page 21 last week a new variety?" The printer's reply to the inquiry is that he "accidentally left the 'hen' out," and goes on to say that if it were a case of nasal infirmity the inquirer would have been confronted with Logpod Bead. He adds as a pendant, "Will your correspondent order a quart or two, and kindly send a dish for our next Beanfeast?"

— **LEE, BLACKHEATH, AND LEWISHAM HORTICULTURAL SOCIETY.**—As briefly announced in our last issue, the twenty-sixth annual meeting of this Society was held on Monday, January 9th, at the Institute, Lee, there being a good attendance of members. The Chairman complimented the members upon the completion of a quarter of a century of useful work, and upon a satisfactory financial statement, which showed a balance in hand of about £31, although a larger amount had been paid away in prizes. The election of the new Committee (twenty-four in number) and the election of the Bishop of Southwark as a member and patron (making the second bishop elected in two years) were then proceeded with. Votes of thanks were accorded to the various officers and special prizegivers, the Press, and the Chairman. At the next meeting, to be held on the 27th inst., a paper will be read by Mr. G. Gordon.

— **GARDENERS' FRIENDS AND ENEMIES.**—This was the title of an exceedingly interesting and instructive lecture delivered by Mr. C. E. Pearson, of Messrs. Pearson & Sons, Chilwell Nurseries, Nottingham, before the members of the Wakefield Paxton Society, at their usual weekly meeting recently. Ald. Milnes and Mr. B. Whiteley, two of the Vice-Presidents, occupied the chair and vice-chair respectively. Considering the exceedingly inclement state of the weather, there was a good attendance. The lecture was illustrated by a large number of photographic views, which were admirably exhibited by the oxy-hydrogen limelight. Mr. Pearson quickly convinced his attentive and most appreciative audience that he thoroughly understood the subject on which he had undertaken to lecture, and that his advice was based on personal experience and practice, and not merely on theory. He exhibited views of a large number of slugs, grubs, caterpillars, and moths in various stages of life, pointed out how and where they generally increase and multiply, referred to the great damage which they do to growing crops, and explained the best means of getting rid of the destructive pests. Mr. Pearson also exhibited views of insects which are the gardeners' best friends, and he strongly recommended his hearers to preserve such insects and toads.

— **MANURES.**—This was the subject of a lecture delivered before the members of the Winchester Gardeners' Association by Mr. A. Dean, of Kingston-on-Thames, under the auspices of the Hants County Council, at the Society's Rooms, on the evening of Thursday, January 12th. There was a large attendance of members, presided over by Mr. Lowndess, lecturer on horticulture for Hampshire. Mr. Vaughan, Cornish Technical Education Secretary, was also present. The subject was dealt with from a gardener's point of view, and was illustrated not only by the aid of diagrams, but also by numerous samples of artificial manure, kindly furnished by Mr. E. Luckhurst and by Messrs. H. and E. Albert, of Gracechurch Street, City, who also sent a large number of Dr. Wagner's admirable pamphlet on plant foods, which were distributed amongst the members. A very hearty vote of thanks was awarded to Mr. Dean at the close of the lecture.

— **DOUBLE CHINESE PRIMROSES.**—I noted several good plants of the Double White Lady, a pure white variety, blooming freely recently at Hackwood Park. Mr. Bowerman marvels that anyone should make so much of the old Alba plena, or even of its improved form, when such varieties as White Lady can be grown so easily and produce such very fine double flowers. When grown well, so as to make really specimen plants as I have seen them done occasionally, the bloom production is relatively treble what can be obtained from the old Double White. By relatively I mean that fully three flowers of the latter are needed to make one of the former. It is not easy to get these plants to grow unless they are thoroughly understood, but then those who do them well find no difficulty in the cultivation. Side shoots make good cuttings in the spring. These are grown on in small pots in sandy loam, helped by one-third old decayed manure. Plenty of light and air during the summer and a gentle warmth in the winter suits them.—D.

— **LARGE TOMATOES.**—I was interested in your answer on the above subject to "E. G. N." (page 40), for I am rather in favour of Ponderosa as a useful and paying variety. The proper colour of it is dark crimson, and a very truthful representation of it is before me now in Messrs. Henderson's (New York) catalogue. But I selected a scarlet fruit out of the first batch of plants I grew, and I find this a large and handsome Tomato of very excellent quality. Most of the fruits weighed from 6 ozs. to 14 ozs., and they certainly were not coarse. Why does Mr. Gilbert exhibit it under name of Royal Sovereign? The continual renaming of one and the same variety leads to no end of mistakes and continual expense. How often have I found when I possessed a good strain of something, and have sent for "Jones' World's Wonder" and "Smith's Eclipse" at high prices, I have, when all came to maturity, found them identical with what I already possessed. How annoying is this! This ought in some way to be amended. A man should have a right in his own introduction—vegetable, fruit, or flowers of his own raising—and gardeners ought to be safeguarded against buying one and the same variety under half a dozen high-sounding names and at high prices. As you truly state, Perfection is the Tomato for exhibiting. It is not a heavy cropper but it is a fair one, and the colour and form cannot be excelled. I see in Henderson's (New York) catalogue a first prize of £30 (150 dols.) was given for Ponderosa Tomato to the grower of a 3 lb. fruit. £20, £15, £10, £7, £6, £5, £4, £2, £1 were given for smaller fruits. These are prizes indeed, and make the English exhibitor's mouth water.—H. S. EASTY.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR THE YEAR 1892.**—Mean temperature of the year, 45.9°; maximum on the 3rd of July, 81.0°; minimum on the 16th January, 7.2°. Maximum in the sun on the 3rd of July, 136.3°; minimum on the grass on the 9th of January, 1.2°. Mean temperature of the air at 9 A.M., 46.5°; mean temperature of the soil 1 foot deep, 46.9°. Number of nights below 32°, in shade, 107; on grass, 183. Total duration of sunshine in year, 1261 hours, or 29 per cent. of possible duration; we had eighty sunless days. Highest reading of barometer on March 30th, 30.680; lowest reading of barometer on 2nd February, 28.926. Total rainfall, 22.22 inches; minimum fall in twenty-four hours on 28th June, 1.32 inch; rain fell on 168 days. Average velocity of wind, 9.1 miles per hour. Velocity exceeded 400 miles on thirty days, and fell short of 100 miles on seventy days. Approximate averages for the year—mean temperature, 47.9; sunshine, 1227 hours; pressure, 29.932; rainfall, 24.54 inches. The year was dry, very cold, but fairly sunny. The mean temperature was lower than in any of the previous sixteen years, except 1879. The only month in which temperature was substantially above the average was May, and it was slightly above in November. In the remaining ten

months it was below the average, in October and December by more than 3°, and in March and July by more than 4°. The nights were especially cold, and the number of frosts large, though the extreme minimum was not exceptional.—J. MALLENDER.

— ALLAMANDA HENDERSONI.—Growing in 9-inch pots in one of the houses at Hackwood Park are three plants of this Allamanda. They stand on the front stage, the growths being trained on wires under the roof. When I saw them a few days since they were blooming freely, and would certainly flower for yet a couple of months. Mr. Bowerman states they had been blooming most profusely since early in June. What a great number of flowers and of what considerable value had they been in the six months mentioned. One reason why the plants had flowered so long was the fact that they were somewhat root-bound, and had been kept in a comparatively moderate temperature.—D.

— RASPBERRY BAUMFORTH'S SEEDLING.—Although the above-named Raspberry is probably well known, I should like to add a word of praise in its favour. I have grown it now for five years, and find it excellent in all respects. It is a free grower and cropper, the fruits of large size and fine colour. Grown side by side with Carter's Prolific and Fastolf it is superior to both. When made into a preserve it is of the most beautiful colour, remarkably rich in flavour, and with an agreeable juiciness, which latter quality is often absent in many varieties when so prepared. I would recommend anyone in request of a good variety for this particular purpose to give it a trial; I am sure they would esteem it most valuable, or, in fact, for any purpose.—J. J. C.

— LECTURES AT THE ROYAL HORTICULTURAL SOCIETY'S MEETINGS.—The following lectures are arranged to be given at the meetings of the Royal Horticultural Society during the current year:—March 14th, "Some Effects of Growing Plants under Glass of Various Colours," the Rev. Professor Henslow, M.A. March 28th, "Flowers of the Riviera," Mons. Henri de Vilmorin. April 11th, "Orchid Life in Guiana," Mr. Everard im Thure. April 25th, "How to Solve Chemical Questions Concerning the Soil without Chemistry," Professor Cheshire. May 9th, "Fritillarias," Mr. D. Morris, M.A. June 6th, "Hardy Rhododendrons and Azaleas," Sir J. T. D. Llewelyn, Bart. July 25th, "Alpine Houses and their Inhabitants," Mr. H. Selfe Leonard. August 8th, "Cannas," Mr. J. G. Baker, F.R.S. September 12th, "Garden Phloxes and Pentstemons," Mr. J. Douglas. September 26th, "Causes of Failure in Eucharis Culture," Mr. W. Iggulden. October 10th, "Pears," Mr. W. Crump. October 24th, "Onions," Mr. A. Dean. November 14th, "Chrysanthemums," Mr. R. Parker. November 28th "Late-keeping Grapes," Mr. T. Crasp.

— THE GARDENERS' ORPHAN FUND.—In your notice in last week's *Journal* under the heading of "Royal Patronage for the Gardeners' Orphan Fund," after announcing the contribution from Her Royal Highness the Princess of Wales (a very gratifying announcement truly) in mentioning other donations there is one of £5 from the Carnation and Picotee Society's Show, Edinburgh. This is a mistake, as there is no Scottish Carnation and Picotee Society, and the donation in question was sent by the Committee of the Midland Counties Carnation and Picotee Society, Birmingham, who at the same time sent a donation of £5 to the Gardeners' Royal Benevolent Institution, both on the proposal of Mr. Robert Sydenham. I should not trouble you to correct this, only as it gives me an opportunity of saying that it is in the power of so many horticultural exhibition committees to go and do likewise in a lesser or larger degree. Last year at a large exhibition under my control we had a special tent and staff of young ladies for the sale of Roses and other flowers purposely to benefit the Gardeners' Orphan Fund and our local children's hospital, but a downpour of rain upset our arrangements; still, as it was we contrived to send £3 to each institution. With fine weather we should have made it fully £10 to each. The Orphan Fund has in our local Secretary Mr. J. Hughes, an energetic worker and friend, and I think I may say that no other local secretary has sent up so much money to the general fund as he has. At many of our exhibitions he has collecting boxes in use, often by intelligent little girls, who ask for contributions, and Birmingham has done some good work for the Orphan Fund. But much more is wanted, and the Gardeners' Royal Benevolent Institution should also be remembered, for both Institutions are truly gardeners' friends and doing an immense amount of good.—W. D. [The error alluded to was purely clerical. It was discovered and a correction made prior to the receipt of this communication, but not now inserted. Birmingham is one of the best supporters of our gardening charities, and Mr. Hughes is regarded as a model local Secretary.]

— MARKET PRODUCE.—I marvelled to read on the testimony of "an authority" that the whole of the vegetable produce of England is grown in the Thames valley and the home counties. Of course enormous quantities are grown in districts remote from London. Probably the authority meant to have said the whole of the English produce sent to Covent Garden or London markets was so grown, but that even would not be entirely correct unless the term "home counties" was to be regarded as very expansive. Middlesex certainly does produce many vegetables and much fruit, but it is a very small county after all. The most remarkable thing is that the County Council does nothing at all for the industry.—A. D.

## IN MEMORIAM.

THE REV. FREDERICK TYMONS.

THE opening days of 1893 have brought with them news that will sadden many a reader of the *Journal* when he learns that that genial, hearty, and enthusiastic florist, the Rev. F. Tymons of Baskin Hill, Drumcondra, Co. Dublin, has passed away, although he was known only to a comparatively small number on this side of St. George's Channel; but in Dublin and its neighbourhood he was well known and deeply valued. His great love for the Auricula at one time brought him frequently to England, and he assisted at the judging of those favourite flowers of his, a capacity in which I have been associated with him. His taste was severe. He had been brought up in the strict school of the Dublin florists who followed the steps of the Lancashire growers, and, as a consequence, the loose notions which at that time prevailed with those who ruled the Society were very distasteful to him. I shall never forget his indignation when, after we had carefully gone through larger classes, we were asked to reconsider our adjudication, and alter it because of the superior way which some were set up! He had no sympathy with what seems too often to be considered the desideratum—a truss with a dozen pips upon it, large in size, and coarse in texture. He was a thorough Irishman, full of the quickness and ready wit which characterises the race; thus on one occasion when he came across a stand on which was quite a second rate flower, St. Agustine, he said, with a merry twinkle of his eye, "Who canonised that Saint?" Equally striking was his protest against the staking of Auricula blooms at the Exhibition, "If they want crutches they had better stay at home." I have mentioned the Auricula because it was through it he was best known to English florists, and because, although he had many loves (as a florist), I believe this flower held the chief place.

I once had the pleasure of visiting him at his pretty home at Baskin Hill, and truly it was the home of a florist, for florists' flowers of all kinds—a small but very choice collection of Auriculas, Pansies, Carnations, Tulips, Dahlias, and Roses, all found a very happy home at Baskin Hill, while he had in his greenhouses very choice and valuable plants, and a fine batch of *Disa grandiflora*. He took the keenest interest in herbaceous plants, and his borders and rockery were filled with choice plants. Never have I seen anywhere such masses of the white Martagon Lily as there; but in truth everything was carefully looked after by the master himself.

He was a constant exhibitor at the Royal Horticultural Society of Ireland's Exhibitions, and a very successful one, and he will be greatly missed there; but he was one of those men to whom the prize was a secondary matter. He loved plants and delighted to see them honoured. And thus another home of the florist is broken up; but his memory will be cherished by many—indeed, by all—who knew him. Mr. Tymons was unmarried.—D., Deal.

## GOODRICH COURT.

AMIDST surroundings of surpassing natural beauty stands the above mansion, the delightful residence of H. C. Moffat, Esq. The Ivy-clad ruins of Goodrich Castle occupy a commanding site well in view of the house, and skirted by the waters of the famous Wye, on their serpentine course, *viâ* the renowned "Symond's Yat." "Aggressive" and "Progressive" are the mottos in gardening matters at Goodrich, and within the last few years an extensive, complete, and conveniently arranged modern garden has been formed on a better site than the old and scattered one. In effecting such a radical change, Mr. Spencer, the energetic and courteous head gardener, has had his hands full, and for purposes of economy, as well as to have as much accommodation as possible, he saw his way to press the old glass structures, or many of them, into the new service, and so well has this been effected that appearances everywhere are as good as new. Conveniences in way of sheds, Mushroom house, stokeholes, and efficient boilers are well provided, also a comfortable bothy for the young men, a matter too often sadly neglected.

The vineries form a splendid range, and the Vines are already giving a good account of themselves, among them Alnwick Seedling, Mrs. Pearson, Duke of Buccleuch, Muscats, with the indispensable Lady Downe's have all done wonderfully well in the short time that they have occupied their quarters. A good border has been made inside as well as out, wherein a prepared compost, a great proportion of which is the rich, native, maiden loam, has been provided at intervals, new portions being added as the roots penetrate that already at their disposal, thus escaping that scouring of the border generally consequent by continual watering on

too great a body of soil. The same rule has been adopted and followed in the Peach range with equally satisfactory results. Thus Mr. Spencer, by adding breadth to his borders occasionally, regulates the growth and also the character of the wood that is made. An abundance of ripe Melons cannot always be seen at the end of October, but here we saw such, also Tomatoes on plants calculated to keep well in bearing through the winter. The Pine Apples suffered by removal from their old quarters, but are fast recovering themselves, and some young sturdy plants are evidently the right sort for producing grand fruit. *Calanthes* occupying shelves in Pine stoves were carrying fine spikes, but our visit was too early for these.

In the Orchid houses proper there was a good display of bloom.

Among *Cattleyas* good plants and forms of *C. aurea*, *C. Gaskelliana*, *C. Sanderiana*, and *C. Skinneri* were noteworthy.

Palms, Ferns, and foliage and flowering plants were thriving in the stove and greenhouses. In one of the latter Mr. Spencer has capital specimens and half-specimens of *Statice profusa* and *S. Holfordi*, clean and healthy, such as are not frequently seen. These have been well grown at Goodrich for years. *Marantas*, *Anthuriums Veitchi*, *Andreanum*, and *crystallinum*, with *Ixoras* and *Dipladenias* as specimens, are pictures of health in the stove, with numbers of young plants for immediate and future use. A batch of Winter Cheer Carnations confirmed all that has been said about this excellent variety. *Lachenalias* were also exceedingly good. These plants deserve to be more generally cultivated. Another plant

FIG. 8.—A VIEW IN THE ORCHID HOUSE AT GOODRICH COURT.

*Laelia purpurata* and some of its varieties, particularly *L. p. alba*, were conspicuous, the plants being exceptionally fine and in excellent health. Indeed, all the plants bear the same stamp of healthiness, and although Mr. Spencer does not pretend to make a specialty of Orchids, the collection is certainly meritorious, and contains several rarities. *Aërides*, *Vandas*, and *Saccolabiums* were equally at home with *Cattleyas*, *Laelias*, *Oncidiums*, and *Dendrobiums*. *Laelia Perrini* was better cared for than we often find it, and *L. albida*, *L. anceps*, and its forms were well in evidence. *Cattleya Bowringiana* was noticeable, and of *Lycastes* there were some very fine forms. There are good plants of *Cypripedium Spicerianum*, one of which we have seen carrying forty spikes. Large numbers of *C. insigne* are grown, and are found useful for cutting and decorative purposes. *Angraecum eburneum* and *A. sesquipedale* both thrive and flower well, as also do *Anguloa Clowesi* and *Stanhopeas*.

noticeable as a trailer or climber was *Tropæolum Clibran's Gem*, of a very dark hue, and sent out by Messrs. Clibran & Sons. Another good thing was *Begonia geranioides*, which, as grown at Goodrich, is a decided acquisition.

A heavy crop of Mushrooms in the new house was shown us. The kitchen garden, though culinary crops were abundant, is only yet in its infancy, and the fruit trees are but young and the walls unfurnished. All, however, are most promising of an early and complete success. The gardener's house is also new, and is such as only a considerate employer would erect for his gardener. In addition to being commodious it also stands in the best possible position for the conditions of health and extent of view.—BRADWEN.

[The illustration (fig. 8) represents a view in one of the Orchid houses at Goodrich Court.]

## CROYDON CHRYSANTHEMUM SHOW.

WE are informed that the Croydon Chrysanthemum Show, being unavoidably postponed, will take place on November 14th and 15th, instead of November 8th and 9th, as already noted.

## GOLDEN WEDDING CHRYSANTHEMUMS.

WE are glad of the opportunity to say to the readers of the *Journal of Horticulture* that Messrs. H. Cannell & Sons, of Swanley, are sole agents for the sale of our grand new Chrysanthemum Golden Wedding in England and on the Continent. We have not sold any stock to anyone else, and will not sell any for the ensuing year.—PETER HENDERSON & Co., New York.

## MRS. LOUIS CHILD MADEIRA CHRYSANTHEMUM.

THIS variety promises to be one of the very best late incurved Japanese yet in commerce. I have now, January 12th, a beautiful bloom on a young plant struck last July. Its colour is that of Mrs. Robinson King, and the flower forms a beautiful golden sphere. In the *Journal*, December 29th, 1892, there is a notice of this variety, and it states that a Mr. R. Craig is the raiser. Such is not the case. This and many other good ones of American origin, such as Marvel, R. C. Kingston, E. W. Clark, Master Bates Spaulding, were raised by my old friend and comrade, Henry B. Surman of Germantown, Philadelphia, U.S.A.—CHAS. LAWTON, *Welton Gardens, East Yorkshire*.

## LYGUS CAMPESTRIS AS AN ENEMY TO THE CHRYSANTHEMUM.

A CORRESPONDENT of "Nature Notes," resident at Acton, reports that he has found the above bug frequently on garden flowers, and says that it seems especially partial to the Chrysanthemum. It is a pretty green insect, and might have passed as harmless had it not been detected in the act of piercing the unexpanded flower buds with its beak or rostrum, thereby causing them to die off. It has apparently, like some other bugs, a taste for what is bitter or aromatic; but it does not attack the buds to deposit eggs upon them. We have no information as yet concerning the early stage of this bug, nor of many more; but some suppose the larvæ may occasionally prey upon other insects, which would be a set-off to the damage done by the mature insect. There appears to be no way of checking it, except the removal of any individuals that may be seen.—J. R. S. C.

## CHRYSANTHEMUMS FOR PROFIT.

I READ "Enfieldian's" useful article, at page 13, with much interest. He speaks of Madame Louise Leroy as somewhat displacing Elaine. I think the former variety decidedly the better of the two, and it is equally as free as Elaine. Each flower, moreover, is perfect, never showing the black centre. Speaking of black centres reminds me that Chevalier Damage has that tendency. I consider President Hyde better in every respect. I also strongly recommend Massalia as a bright crimson; it is much freer than Cullingfordi, though that variety should not be despised, as it is grand in colour and some days earlier than Massalia, which makes the latter of more value really. We have Massalia good now; it produces more blooms on a spray, while it carries its flowers well, the stems being stout. We have grown the two side by side, and Massalia certainly produced double the supply of its neighbour, which is saying much in its favour. Another variety I would like "Enfieldian" to try is Frank Wilcox, for late work; it is a reflexed variety, bright golden yellow, and overlaid with bronze; a most showy and attractive flower, very free, strong grower, and dwarf in habit; requires but little staking. For earlier work Gloire du Rocher will prove good, as it is very free and showy, being much the colour of Val d'Andorre, without the stiffness attending the latter kind. Florence Percy (white) is well worth growing, and should be in all collections where cut flowers are a speciality; it is very free, and the individual blooms have a whorled appearance, making it quite distinct.—J. PITHERS.

## JOHN LAMBERT CHRYSANTHEMUM.

HAVING carefully watched this wordy duel, I am greatly surprised at Mr. Molyneux's answer to Mr. Lambert's straightforward question. To my mind Mr. Molyneux evades the real point at issue, which, I think, is this. Did Mr. M. or did he not erase the name "John Lambert" and substitute that of "Golden Queen of England" to the champion incurved bloom in Mr. Coombes's stand at the last Hull Show? If so, what justification had he for so doing?—A YORKSHIRE BITE.

MR. MOLYNEUX accuses me in his last note (page 37) of being wide of the truth; let him first prove this. I have proved this case at Hull against him. He mentions Liverpool where we judged, and left John Lambert as we found it, and had he acted in this way at Hull these lines would never have been written. Let Mr. Molyneux act fairly, and treat this like it is treated by all other Judges and at the National shows, and I am content; but if he still persists in going on one side

to insult this variety he will find me on the war track as often to defend my progeny. At Birmingham in 1890 Mr. Molyneux judged, and for John Lambert, as shown by me in my first prize stand in the open class, Golden Queen is reported to be shown, and not John Lambert. This report is corrected in your *Journal*, page 496, December 4th, 1890. Notwithstanding the opposition of Mr. Molyneux to this sport, it has gained public favour, and when such men as Messrs. Parker, Blair, Doughty, Shoesmith, Goodacre, Coombes, and many others, show it in preference to Golden Queen of England it is a proof of its superiority, and your other correspondents unknown to me think it is not treating it fairly.—JOHN LAMBERT, *Powis Castle*.

## HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY.

THE ninth annual meeting of the Hull and East Riding Chrysanthemum Society was held on January 11th, at the Royal Station Hotel, Mr. R. F. Jameson in the chair, when the report and balance-sheet for the past year was received and adopted, and the officers and Committee for the ensuing year were elected. The report was of a most satisfactory nature. Over 10,000 visitors of all classes were admitted to the Show in November last, and the exhibits generally were of a very high order of merit, whilst the balance-sheet showed that a profit of over £52 had been made on the year's working of the Society. Funds in hand now amount to £341. Votes of thanks were unanimously passed to the Mayor and Sheriff for their generous gifts of a silver cup each, value five guineas, for competition at the next Show, as also to Mr. James Reckitt, of Swanland Manor, who had promised to give a silver challenge vase, value 20 guineas, in the class for a group of Chrysanthemums interspersed with foliage plants. It was also announced that Mr. Harold Reckitt had promised to give a prize, value five guineas. The officers and Committee were elected as follows:—Chairman, Mr. R. F. Jameson; Vice-Chairmen, Messrs. George Bohn, Captain Brodrick, Major Dibb, and James Reckitt; Hon. Treasurers, Messrs. Charles Judge and Thos. G. Milner; Hon. Secretaries, Messrs. Edw. Harland and James Dixon; Committee, Messrs. A. S. Ayre, W. S. Brodrick, G. Cottam, jun., J. H. Fisher, E. Goddard, Allen H. Hall, F. W. Jameson, R. E. Johnson, R. W. Judge, G. A. Haldane, A. W. Stanley, and W. Wheatley. Messrs. George Duncan and W. H. Wood were re-elected Auditors. Messrs. G. Gordon, E. Molyneux, and J. Wright have been desired to officiate as Judges on November 15th and 16th.

## THE BEAUTY OF EXMOUTH CASE.

I AM surprised to find (page 37) Mr. H. Cannell asserting that I am "dissatisfied with the Chrysanthemum people generally." Will Mr. Cannell be good enough to state upon what evidence he makes such an assertion? and I deny most emphatically the insinuation that I am one of those persons who "find fault with the world generally." Like Mr. Cannell, I have no reason to do so. I agree with him to the extent that the "Beauty of Exmouth" case is bringing discredit on the N.C.S., but the blame rests, not on my shoulders, but rather on that of the Society in question through a glaring indiscretion of one of its Floral Committeemen and the way it has been met.

Permit me to inform Mr. Cannell that I am just as anxious to "denounce anything discreditable or unfair" as himself, and it was this feeling which prompted me to act as I have.

I stated in my first letter (page 418, November 10th, 1892) that it was Mr. Cannell who requested that a bloom of Florence Davis be brought to the table, and I am not aware that anyone has disputed that statement, and I believe Mr. Cannell had the best of motives in acting as he did. Again, no one has questioned the number of times that he or any other member has attended the meetings or the lack of interest they have shown in the Society. Surely Mr. Cannell has not read my first letter to the *Journal*.

Will you grant me space to repeat shortly that prior to my blooms being placed before the F.C. for certificate a member ridiculed them in a most unbecoming manner, and this in the presence of several members of the F.C. Was this in his business capacity, Mr. Cannell? In Committee he voted twice against the granting of a certificate. This he had a perfect right to do if he thought the variety did not merit the honour; but he afterwards wished to purchase the whole stock of the variety at a big price, and getting a negative answer from me, inquired the price per 100, "as such a variety as that was bound to sell," adding his reason for voting against the granting of a certificate was because Beauty of Exmouth would cut out one of his introductions.

These are the circumstances which Mr. Cannell says call for no inquiry. If this be his idea of what is strictly right and proper I fear it does not merit such an amount of self-laudation as is bestowed upon it.

Mr. Harman Payne's remarks *re* the Beauty of Exmouth call for a reply from myself. Will Mr. Harman Payne be good enough to state why the Committee could not investigate this case without fear of incurring a libel suit, the same as the "Wells" case was gone into? First it was, "We can do nothing until the alleged offender's name is published;" now the cry is, "We fear a libel suit." I agree with Mr. Harman Payne when he says, "There ought to be a preponderance of evidence on one side or the other, and not an equality." It is for this reason I urge a thorough investigation, and let it be continued until I am proved right or wrong.

I should scorn to shelter myself behind the "law," or to take advantage of any of its technicalities. I am perfectly willing, as Mr. Fowler suggested at the General Committee meeting (reported on 553 December 23rd) to "waive any legal right," and I am also willing to sign an undertaking not to prosecute anyone for anything he may say in an

investigation to prove me wrong. That is what General Booth did, I believe, prior to the investigation into his case, and I cannot conceive of anyone who is not ashamed of the truth hesitating for a moment to do the same, and act in full accordance with Mr. Fowler's proposition, which is just such a one as we might expect from a high-minded gentleman. Has Mr. Cannell anything to say against it?—W. J. GODFREY, *The Nurseries, Exmouth.*

#### INCREASED SIZE OF STANDS.

MUCH has been said of late as to the desirability of increased space for the full display of the Japanese blooms. From the reports published the Conference recently held under the auspices of the N.C.S. regarding this matter, has been by the action of the General Committee of that Society rendered nil. Although the meeting of October 12th was almost unanimous in its decision that the time had come when an increase was imperative. I approve of the action of the General Committee in not making the rule absolute. At the same time, I think many stands of blooms would be the better if more space was allowed, but to compel those who do not favour the extremely large and spread-out examples of some exhibitors to adopt a larger stand than the orthodox one would be unfair. We cannot legislate for a few to the detriment of the mass. The former, under existing conditions, have their remedy, but few Societies now-a-days limit the size of stands for the Japanese blooms. None ought to do so; if this were the rule all classes would be met. No one could then complain of defective judgment owing to the blooms not having space to show themselves.

If there is an advantage in giving more space to the larger blooms, surely the smart exhibitor would not be slow to avail himself of the opportunity. All that is wanted is a few object lessons from some of the leading exhibitors, distinctly showing the advantages there are to be gained by the use of larger stands, and if others do not follow suit I shall be very much surprised. Nothing could be more objectionable than small or even medium-sized blooms displayed on stands much too large for them. Not only is the exhibitor at a disadvantage, but the Society is compelled to provide table space in excess of the requirements of the case.

Personally, I do not believe in conferences, at least not for the amount of good that is supposed to emanate from such meetings. That they are very pleasant gatherings I do not doubt, but instead of so many of these I consider that a few practical object lessons at some of the leading shows would do more towards achieving an object than much talk. What has brought Chrysanthemum culture to its present state? Nothing but object lessons. I daresay, if those who go about the country during the exhibition season were asked how many stands at each Show needed an increase of size, the answer would be not more than five out of every fifty. At least this is my impression gained from the few shows that I see during a season. Let all societies allow an extension for the Japanese blooms, but let it be optional and with a provision as to the limit of the extension. It would never do to allow all to employ whatever size they thought fit. The compilation of the different sizes suggested by exhibitors in a contemporary a short time since proved the fallacy of this plan. While some were content with a slight increase upon the present size, a few others went in for a great reform.—SADOC.

#### NEW CHRYSANTHEMUMS.—(Concluded from page 38.)

THE Japanese varieties are becoming so numerous that some judgment is required to make a selection of the best. The incurved forms predominate, and some of them are scarcely to be distinguished from the strictly incurved varieties.

*Emily Doone.*—This is a charming variety, centre creamy white, shading to soft pink in the outer florets. I consider this an improved Puritan when properly grown.

*Fred Dorner.*—Clear primrose yellow, with a faint salmon tint on the outer florets, reflexed in form, a fine bold full flower, quite up to exhibition form; dwarf habit and very free.

*Mermaid.*—A grand solid bloom with stout pointed incurving florets, delicate cream colour shading to pink; a strong grower, 5 feet 6 inches in height, requires stopping about the middle of May.

*Mistletoe.*—This is quite distinct, a large incurved flower of good form, colour delicate silvery pink, very full, and will make a good exhibition bloom. Our best blooms were from plants struck in March, taking the first bud. These plants were grown in 7-inch pots, and were about 2 feet in height.

*Mrs. J. R. Baylis.*—A large incurving bloom, colour clear golden yellow striped chestnut red, florets very broad and of rare substance. It will make a grand grouping plant; it seldom exceeds 2 feet 6 inches. The plants should be stopped about the 1st of May.

*Robert Flowerday.*—This is another incurved Japanese of immense size, very broad florets, colour rich crimson purple, with silvery reverse. A grand show bloom, strong grower; height 5 feet. Should be stopped the first week in May.

*John Dyer.*—This variety has some promise about it. Colour yellow, overlaid with bronzy red. A fine bold bloom, strong grower; height 5 feet 6 inches.

*John Farwell.*—This has been grand with us. Colour of the richest crimson, the florets drooping after the fashion of Sunflower; quite up to exhibition size. Some growers have failed with this kind by taking the buds too early. To get it at its best the plants should be cut back about the end of May or struck late. The blooms requires plenty of heat to develop properly.

*Mrs. E. Beckett.*—A handsome white variety, the flowers composed of long twisting drooping florets. A grand show bloom, distinct. It is a very strong grower, of dwarf habit.

*Mrs. H. W. Goulden.*—When well finished the bloom of this is typical of a good incurved, for which it was often taken last November. Outside of florets soft blush pink, inside deep lilac; a tall grower.

*REFLEXED.*—*A. J. Banks.*—A charming pretty flower, primrose yellow; rather small, but will prove a very useful decorative variety; a sport from Felicity, but a fuller bloom.

*R. Smith.*—This is a mahogany coloured sport from Dr. Sharpe. The colour was much wanted in this class, and this variety should be in every collection where reflexed blooms are a speciality, as it possesses all the merits of its parents.

*ANEMONE-FLOWERED.*—*Delaware.*—This is decidedly one of the very best large-flowered Anemones that has appeared for some time. This variety will produce half a dozen blooms on a plant, each flower being 6 inches across. The guard florets are white, cushion pale primrose. A remarkably strong grower, though of dwarf habit.

*ANEMONE POMPON.*—*Emily Rowbottom.*—A beautiful white sport from Marie Stuart, but has a better cushion than its parent. A most useful kind either for exhibition or for cutting.

*POMPON.*—*W. Saby.*—A bright golden yellow—an excellent kind for cutting.

*SINGLE.*—*Mrs. Charles Seeley.*—This was raised at Chilwell. It is most distinct in colour and of good form, the colour is of a delicate creamy white, keeping good a long time.—J. PITHERS.

#### ROYAL HORTICULTURAL SOCIETY.

JANUARY 17TH.

THE Drill Hall was not full on the occasion of this, the first meeting of the year; but a fair display of Orchids, groups of Cyclamens, Daffodils, winter Begonias, Chrysanthemums, and a large collection of Apples made up an attractive Exhibition.

**FRUIT COMMITTEE.**—Present: P. Crowley, Esq. (in the chair), with Rev. W. Wilks, Arthur Veitch, G. Bunyard, J. Cheal, Harrison Weir, G. W. Cummins, T. J. Saltmarsh, G. Burrell, A. Dean, A. H. Pearson, G. Norman, H. Balderson, C. Ross, G. Wythes, J. Hudson, G. Sage, A. J. Laing, G. Reynolds, and J. Wright.

Prior to the commencement of business the Chairman, in a few pleasant words, welcomed the members, making special allusion to the new ones, and trusted that good and harmonious work would be done by the Committee during the year. Mr. Crowley's good wishes were cordially and unanimously reciprocated.

The first duty of the Committee was to examine a number of seedling Apples sent by Mr. Becker from Jersey, but all of them were decidedly inferior to the best varieties in general cultivation. Mr. J. Butler, Broke Hall, Nacton, sent a seedling Russet Apple, which was not in good condition nor represented by the requisite number of fruits, and was passed. Mr. Barron placed on the table large handsome fruits of Blue Pearmain Apple, an American variety, symmetrical in form, distinct in colour, tender and pleasantly flavoured. Tree a good bearer (award of merit). Mr. R. Maher sent a dish of Stamford Pippin Apple, medium sized, sharply flavoured fruit. He also sent a dish of transparent-looking Apples of attractive appearance, decided to be Winter Peach (vote of thanks). Mr. Turton, The Gardens, Maiden Erlegh, sent a dish of Annie Elizabeth Apple, fine firm fruits, a long-keeping variety, but the tree is a shy bearer till it attains age (vote of thanks).

Mr. A. Dean placed a dish of very fine Oranges on the table grown in Palestine, and known in the market as Jaffa Oranges because they are shipped from Jaffa. The fruits were large, oval-shaped, seedless, and good, but these Oranges are better later in February and March. Mr. H. Balderson was awarded a cultural commendation for a dish of Asparagus, white but tender. Mr. Balderson obtains a supply of Asparagus, Seakale, and Rhubarb in winter in a very simple way. He has abundance of tan at command, makes an excavation in one of the heaps in the open air, places in the roots, covers them with soil and the soil with straw, and thus produces the crops.

Mr. G. Bunyard exhibited a magnificent collection of Apples, 150 dishes, the fruits being in the best possible condition, and many of them exceptionally fine. Bismarck, Mère de Ménage, Bramley's Seedling, Warner's King, Lane's Prince Albert, Waltham Abbey Seedling, Peasgood's Nonesuch, Lord Derby, and Tower of Glamis were a few out of many that elicited general admiration. A silver-gilt Knightian medal was unanimously recommended. Messrs. Cheal & Sons staged a much smaller and interesting assortment of Apples not generally grown, and a medal was recommended.

**FLORAL COMMITTEE.**—Present: W. Marshall, Esq. (in the chair), Messrs. W. C. Leach, R. B. Lowe, J. Jennings, George Phippen, H. B. May, C. F. Bause, E. Molyneux, R. Dean, Robert Owen, W. Herbst, John Laing, George Paul, Harry Turner, Charles Noble, Charles E. Shea, Peter Barr, Frank Ross, C. J. Salter, Walter Furze, Thomas Godfrey, Edward Mawley, George Stevens, and Owen Thomas.

Messrs. Hugh Low & Co., Bush Hill Park Nurseries, Enfield, staged a very fine collection of Cyclamens of various colours. The plants were sturdy and excellently furnished with firm, substantial foliage and well shaped flowers. A silver Flora medal was recommended for this group. Messrs. William Cutbush & Son, nurserymen, Highgate, showed some splendid Dracænas, including *D. Massangeana* and *D. Lindenii*. A bronze Banksian medal was recommended for the latter variety. Messrs. E. D.

Snuttleworth & Co. of Fleet, Hants, showed Narcissi in pots, prominent amongst which were N. Countess of Annesley, Henry Irving, Ard Righ, and obvallaris. The same firm also staged two pots of the charming Iris Bakeriana, and also a pot of Hyacinthus (Muscari) azureus. F. B. Roger Tillstone, Esq., Mouse Coombe Place, Brighton (gardener, Mr. Anderson), sent a group of Narcissus Telamonius plenus (common double Daffodil), which were excellent, when the earliness of the season is taken into consideration.

Messrs. Veitch & Son, King's Road, Chelsea, showed a box of Rhododendron javanico-jasminiflorum, hybrids in varieties, amongst which were some lovely shades of colour. Begonia Winter Gem was also shown by the same firm, the flowers being of charming colour. In the same pan with the Begonias were a few plants of Primula floribunda. A vote of thanks was accorded. Mr. W. C. Leach, The Gardens, Albury Park, had a group of Chrysanthemums and Poinsettias, set off with foliage plants, which produced an excellent effect. A silver Banksian medal was recommended. Messrs. H. Cannell & Sons, Swanley, Kent, sent a small group of Chinese Primulas, which had been splendidly grown, the flowers on the majority of plants being large and of excellent substance.

A vote of thanks was accorded to Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, for a basket of Carnation Winter Cheer, the plants being of good habit and finely flowered. For a basket of Pteris Reginae the same exhibitor was again accorded a vote of thanks, an award of merit being given him for a grand plant of Pteris serrulata gigantea. (See below.) Mr. Jennings, gardener to Leopold de Rothschild, Ascott, Leighton Buzzard, staged a magnificent group of Begonia Gloire de Sceaux, and a silver Banksian medal was recommended, also a first-class certificate awarded. (See below.) A group of Tree Carnations, Sir Hy. Calcroft, were also exhibited by Mr. Jennings. Mr. Godfrey, Hillingdon, Uxbridge, showed some flowers of Chinese Primulas which were very good, especially noticeable being a fine white and The Queen. Mr. Owen, Castle Hill, Maidenhead, sent a box of very good Primula flowers of various colours, also several Chrysanthemums. (See awards.)

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair). Messrs. H. M. Pollett, Hugh Low, T. W. Bond, Henry Williams, E. Hill, J. Jaques, Dr. Masters, Jas. Douglas, A. H. Smee, and F. Sander.

Messrs. Hugh Low & Co. had a group of Saccolabium bellinum, a quaint and pleasing little Orchid that is grown by few so extensively or well as by the Clapton firm. Messrs. B. S. Williams & Son contributed a mixed group of considerable beauty, Cypripediums showing up strongly in it. C. Ashburtoniae expansum, C. nitens, C. Lecanum superbum, C. Pitcherianum, Williams' variety, and several varieties of C. insigne were conspicuous amongst them. Cattleya Percivaliana, Odontoglossum Roezli were also noteworthy (silver Banksian medal). Messrs. J. Veitch & Sons sent Cypripedium Penelaus (first-class certificate, see below) and Cypripedium × Godseffianum, the latter a hybrid between C. hirsutissimum and C. villosum Boxalli, is richly coloured, leaning decidedly to the former (pollen) parent in form, particularly in the petals. The Chelsea firm also sent Phalaenopsis × Vesta (P. rosea leucaspes × P. Aphrodite), Cypripedium × Lathamianum, Cypripedium × Creon, Zygocolax Veitchi (Colax jugosus (pollen) × Zygopetalum Mackayi var. crinitum, Cypripedium × Germinyanum (award of merit, see below). Calanthe × gigas (first-class certificate, see below), Cypripedium × Phædra (award of merit, see below), Phaiocalanthe Sedeniana albiflora (Phaius grandiflora × Calanthe vestita rubra oculata), Cypripedium × macrochilum, Epidendrum × Endresio-Wallisi, Cypripedium × Aeson, and C. × Orion. Altogether a collection of exceptional interest. From the Botanical Gardens, Glasnevin, came Bulbophyllum comosum, for which a botanical certificate was awarded.

Messrs. F. Sander & Co. sent a small group but of much interest. It included the beautiful St. Albans variety of Cypripedium nitens, Pleurothallus ornatus with small dark purple white-fringed flowers, Sarcopodium Godseffianum with its curious yellow, purple-spotted flowers and hinged lip, illustrated in the *Journal* for January 8th, 1891, Lælia anceps gemma, Cypripedium Cœnona (Hookeræ × Veitchi), and Masdevallia Hincksiana. R. Young, Esq., sent the richly coloured form of Lælia anceps named plumosa. C. Ingram, Esq., contributed Cypripedium Lindleyanum superbum, and W. W. Mann, Esq., Ravenswood, Bexley (gardener, Mr. Simmond), sent a remarkable plant of Cynoches pentadactylon (first-class certificate, see below). Messrs. W. L. Lewis & Co. received a botanical certificate for Cynorchis grandiflora.

#### CERTIFICATES AND AWARDS.

*Cypripedium* × *Phædra* (J. Veitch & Sons).—A hybrid between C. Lindleyanum (pollen parent) and C. Sedeni candidulum. In form and colouring this hybrid follows the seed parent closely, but the lip may be a little darker. The petals are twisted, soft rose, with lighter central stripe (award of merit).

*Calanthe* × *gigas* (J. Veitch & Sons).—A hybrid between C. Sanderiana gigantea and C. vestita grandiflora. It is of great vigour and beauty, having a bold spike containing numerous flowers. The sepals and petals are ivory white and the lip rich rose (first-class certificate).

*Cypripedium* × *Germinyanum* (J. Veitch & Son).—This is a hybrid between C. hirsutissimum and C. villosum; the former, being the pollen parent, is noteworthy for its narrow dorsal sepal and lip. The petals are those of C. hirsutissimum. The dorsal sepal is shining purple edged with green (award of merit).

*Cypripedium* × *Penelaus* (J. Veitch & Sons).—A hybrid between C. caudatum Lindenii (pollen parent) and C. calurum. This is a note-

worthy acquisition, being very remarkable for its large and massive lip which is of a bright greyish rose. The dorsal sepal is long, narrow, and pointed, greenish yellow in hue. The petals are long, drooping and twisted, soft rosy pink, and impart a most graceful appearance to the flower. It is one of the finest hybrid Cypripediums seen for a long time (first-class certificate).

*Cynoches pentadactylon* (W. W. Mann, Esq.).—A very fine plant of a remarkable Orchid. There were three flowering pseudo-bulbs, the largest being nearly a foot long and more than an inch in diameter. It bore five drooping sprays wreathed in bloom. The flower has narrow sepals and petals, white barred with reddish chocolate; the lip is narrow and clawed, the column curving upwards below it (first-class certificate).

*Chrysanthemum Mrs. E. D. Adams* (R. Owen).—A large Japanese, with long narrow florets, pink shading to white (award of merit).

*Chrysanthemum New Year's Gift* (R. Owen).—An English seedling of the Japanese class, with large flattish creamy white flowers (award of merit).

*Begonia Gloire de Sceaux* (L. de Rothschild, Esq.).—A grand decorative Begonia, having ample dark bronze-green foliage and large clusters of beautiful pink flowers. In growth it is upright but compact, and very vigorous. It is a sterling plant that Mr. Jennings has done well to show in such splendid condition (first-class certificate).

*Pteris serrulata gigantea* (H. B. May).—A large spreading form of slender graceful habit of growth (award of merit).

*Apple, Blue Pearmain* (Mr. Barron).—An American variety of good form, distinct in colour, flesh tender and pleasantly flavoured (award of merit).

#### NOTES FROM IRELAND.

STRAFFAN HOUSE, Co. Kildare, is a pleasant run of some fifteen miles to Straffan Station on the Great Southern and Western Railway. Kingsbridge terminus, Dublin, the starting point, is a noble structure, and, all things in keeping, one might fancy themselves at one of the big London termini, were it not for a superabundance of official shouting, whistling, and gesticulating, seemingly indispensable to the starting of an Irish train. We are now off, and passing the Company's works at Inchicore, reminding one of Swindon on the Great Western Railway, on through a flat country of marked agricultural character, rich looking and pleasant to the eye of the fox hunter, on the far left a low-lying chain of hills, continued from the Dublin mountains, a gradual toning down of the wild scenery of Wicklow and South Dublin to the plains of Kildare, flocks of green plover wing their way over the level lands on the right. Near Straffan Station, one of the last links in the chain of hills is Lyons, with its Fir-clad slopes, the residence of Lord Cloncurry.

From the station we have a drive of twenty minutes on a good road between high Thorn hedges, under-carpeted with the greenest of moss; on over the bridge spanning the Liffey, from which is a delightful peep of the mansion standing on the north bank of the river to which the lawn slopes. A placid looking river is the Liffey this autumn day, but apt to show its temper in a flood by swallowing up the lawn for a few hours, leaving as it recedes a deposit of mud and debris which is not wanted and carrying off the gravel from a boundary walk which is. A drive up the avenue to a side walk leading to Mr. Bedford's house, the model of what a gardener's house should be, covered with Clematis and Roses, conspicuous amongst which is Rêve d'Or; a low stone wall partly enclosing the house is capped and pocketed with a variety of choice bits of alpine, each with its neatly written tiny zinc label, all the work of Mr. Bedford's sons. A dark day in November is not the best time to trespass on one's friends or see much outside; but all that is good or rare in herbaceous plants is here, as we scan the borders en route for the houses. Some special bits are favoured with a zinc collar, others crowned with a cap glass, while others like the Liffey defy all bounds. Some time since I was admiring *Linaria pallida*, and not having it of course begged a bit, and got it with a most emphatic caution that it was a curse, and would overrun the garden. Well, I will forgive it if it does.

The plant houses are numerous and the collection of plants increasing yearly by leaps and bounds, for the Hon. Mrs. Barton and her well-known *chef des jardins* are always on the alert for something new appearing. Amongst such a choice collection any chance visit will see something special. This time it was a group of *Vanda cœrulea* with noble spikes of a dozen flowers, while near are some bits of *Cattleya labiata* in flower, one a particularly fine form. But the Vandas are a feast in themselves; in fact, an act of Vanda-lism to leave them till well photographed on one's mind. A fine batch of *Calanthe vestita* in its two forms was striking. But Orchids here are a special feature; the cool section abundant and happy-looking, but the celebrated Straffan Disas I forgot to ask for, though doubtless my old friend has a frame full in some snug corner—for to do Straffan properly one must look well into the nooks.

Ferns are numerous and fine, *Adiantum palmatum* in a basket arresting attention by its noble Farleyense-like pinnæ hung on pendant thread-like stems. But the cream in this class is a huge *Drynaria diversifolia* 6 feet across, also in a basket. Of this plant the late Dr. Moore of Glasnevin said he would travel round the world if they would give it to him when he came back; but the worthy Doctor has gone a longer journey, whilst his favourite still flourishes. Another giant

foliage plant is *Anthurium Veitchii*, with its grand foliage yearly increasing in size, its latest achievement being a leaf  $5\frac{1}{2}$  feet long. Poinsettias are all that could be wished, and, now the "mums" are waning, doubly useful; but in flowering line I see nothing to compare with that glorious harmony in blue of the Vandas—*chaqun à son goût*.

On leaving the plant houses we come into the kitchen garden of some 7 acres, through the centre of which runs a wall with lean-to range of fruit houses. These give a plenteous supply of Peaches, and the bulk of the Grapes come in when the big shooting parties take place. Facing the centre of this range is a large space of geometrically designed beds, mostly used for carpet bedding, to which a good deal of attention is paid here, while in front of the mansion on the slope to the river is a garden of the Italian pattern, filled in summer with the less tender things than *Alternantheras*. These gardens, in their season, are being filled with spring flowers.

Farming at Straffan is extensive, the Major taking as keen an interest in it, and in his shorthorn pedigree herd, as Mrs. Barton does in the gardens. On one occasion, some years since, Mr. Milne, the steward, trotted out some of his beauties, yearling bulls, for inspection, of which there is an annual sale, splendid sleek-coated creatures, with a habit of frisking up in your front or rear for notice in the way of poll scratching, and as we stood in a narrow way between the two rows of stalls I must confess to a feeling of relief when this part of the programme was over.

The climate here is a somewhat trying one, spring frosts extending often into summer; and my old friend, Mr. Bedford, leads a busy life, beginning the day early and finishing it with nocturnal rambles by lamplight. Seldom from home, one must think themselves favoured if you get one visit from him in return for three to Straffan, but he has the satisfaction of knowing that Major and the Hon. Mrs. Barton are not only good and generous employers, but in a recent severe bereavement have been to himself and Mrs. Bedford the kindest and most sympathising of friends.—E. K.

### POPULAR HORTICULTURE.

OFTEN in a wide and varied experience have I been impressed by the humanising influence of horticulture, but never more so, perhaps hardly ever so much, as upon the occasion of the annual meeting of the Beddington, Carshalton, and Wallington Horticultural Society, to which I went with my old friend and new neighbour, Mr. John Wright. His connection with this Society is of old standing both as judge and adviser, and the frequent appeals made to him during the meeting told me better than anything else could how highly his advice was valued.

We were early at the meeting, and it was as pleasant as interesting to watch the assembling of subscribers, gardeners, and allotment holders; to hear the cheery greetings as one after another came into the bright, warm room out of the dark, cold, snowy night, and to mark how the softening influence of fondness for a garden tells upon all classes, creates a community of interest, brings out the better nature of all who yield to its influence, forming a common ground of meeting, most pleasant for the moment, most beneficent in its effect upon the lives and character of all.

Under the genial presidency of Mr. A. H. Smee the business of the meeting was got through expeditiously and agreeably. The warm interest which he takes in the Society was apparent not only in the discussion of ordinary matters, but also in the proposal of novel and special prizes for the Show to be held on the next August Bank Holiday. Calling attention to the fact of the vegetables shown by professional gardeners and allotment holders last August being alike so excellent that the Judges had so much difficulty in coming to a decision that pointing had to be resorted to, he proposed an amalgamation of all classes, and letting them "fight it out," "and," said he, "I am by no means sure the allotment holders won't have the best of it." This proposal caused some excitement and amusement, and after much discussion it was decided to retain the existing separate classes, and to adopt a new one as an open to gardeners, amateurs, and cottagers, as a champion class. The proposal is undoubtedly excellent, admirably calculated to act as an incentive to all classes of cultivators in the neighbourhood, and to bring together one of the most interesting group of exhibits in the Show.

In addition to existing prizes for cooked Potatoes, home-made bread, jam, bottled fruit, fruit jellies, and honey, Mr. Smee offered to give £5 in four prizes for the best dinner for a man, wife, and three children at a total cost of 2s. This is a challenge to cottage economy that will put many a worthy housewife on her mettle, and as coming within the province of a horticultural society, vegetables and fruits should be encouraged as much as possible in such a competition, but meat is to be included, and the cost of the articles stated.

A fine day for the last show brought so much gate money as to enable the Treasurer to announce a handsome balance, and the proposal which it enabled him to make of granting an honorarium to Mr. G. W. Cummins, the Secretary, in recognition of his services, was received so well by the meeting as to show how much his work for the Society is appreciated. Both Mr. Smee and Mr. Wright spoke highly in praise of the allotment holders, of the excellence of the crops and system of cropping, so that in a variety of ways it was evident the Society was doing good work—work, be it said, of the highest importance, as tending to promote industry, thrift, good management, as well as kindly feeling and self respect.—EDWARD LUCKHURST.

### PSORALEA PINNATA.

FOR some reason many of the old-fashioned hardwooded plants have fallen into abeyance, and it is seldom that they are now seen in greenhouses. This is particularly the case with the *Psoraleas*, amongst which *P. pinnata* (fig. 9) is one of the best. When in bloom this species is really attractive, and should be more generally grown.

It is a compact shrub, attaining a maximum height of 4 or 5 feet, but is seldom seen so large as that. The leaves are neatly pinnated, with three or four linear pinnae. The flowers are produced freely but singly on short pedicels from the axils of the leaves near the upper parts of the growths, their colour being a bright blue, shaded lighter or

FIG. 9.—PSORALEA PINNATA.

nearly white in the centre. A compost of peat and loam, with the ordinary treatment of Cape plants grown in a greenhouse, suits the plant, and it can be propagated by cuttings.

### FUCHSIAS.

WHERE it is desirable to raise a young stock of Fuchsias every year, no time should be lost in placing a few old plants in gentle heat, keeping them well syringed with tepid water to assist in hastening the production of young growths for the supply of cuttings. Cuttings of young growing shoots that are free from flowers root readily at almost any season of the year. As soon as the shoots have two or three joints they may be inserted in light soil, about four or five in a 3-inch pot, and placed in a warm propagating frame. Where this is not available it is a good plan to insert them in a box sufficiently deep to allow a sheet of glass to be placed over them, placing the box on a gentle bottom heat. Where this plan is adopted the glass should be taken off every morning, and the condensed moisture wiped off, or the cuttings will be liable to damp.

When rooted the young plants should be removed from the propagating frame for a day or two before potting them separately, otherwise they receive two severe checks together, which must be avoided if possible, as severe checks, especially when the plants are young, are detrimental to their well-being for the remainder of the season. When well rooted they should be placed singly into 3-inch pots, and put in a temperature of from 55° to 60°, allowing a rise by sun heat.

Wynne were appointed scrutineers, and later in the afternoon declared the poll, those with an asterisk prefixed being elected pensioners of the Institution. The total number of votes polled was 42,337.

John Butler, 1559; Jane E. Nichols, 1156; \*W. Coleman, 1992; \*James Munro, 2375; \*H. Woolford, 2147; \*T. H. Bowler, 1860; \*Henry Bridden, 2975; Clara E. Brown, 612; John Collier, 184; Henry Fielder, 725; Emma Kendall, 1240; \*George Macintosh, 2932; Ann Nixon, 587; \*James Ricks, 2160; Thomas Thomas, 1030; \*Samuel Tisdale, 2137; \*George Woodgate, 2183; Francis Woodhams, 737; Thomas Bundy, 97; James Clarren, 514; John Comber, 674; David Cornell, 34; Hester Falconer, 147; Thomas Gooch, 845; \*Mary Gray, 2012; John Guyett, 1113; William Hale, 49; Ann Harding, 633; \*Margaret Kefford, 2837; Richard King, 475; \*Agnes Merritt, 1931; Ambrose Minty, 170; John Pearcey, 131; Robert Pettit, 601; James Strachan, 129; Eliza Webb, 252; William Pamplin, 760.

#### THE "LARK PUDDING" DINNER.

This gathering, held in connection with the annual general meeting of the Institution, took place at the same hotel in the evening of the 17th inst. H. Seymour Foster, Esq., M.P., occupied the chair, and he was supported by a large company of members and their friends, nearly a hundred sitting down to the table. Amongst those present were the Rev. W. Wilks, H. J. Veitch, Esq., N. N. Sherwood, Esq., J. Weeks, Esq., Messrs. G. Bunyard, J. Laing, A. Veitch, P. Barr, A. Watkins, J. Hudson, G. Woodgate, and numerous other well-known horticulturists.

The Chairman, after the customary loyal toasts, gave that of the evening—namely, "The Gardeners' Royal Benevolent Institution; its continued prosperity and usefulness." In proposing this toast he said it was an excellent custom to hold this gathering after the annual meeting so that the friends of the Institution could go back imbued with fresh zeal. He had left an agricultural conference at Ipswich that afternoon on purpose to be present. Regarding the work of the Institution, he observed that in its first year the annual income was but £100, whereas last year, according to the report, it reached £3527. He noticed also that between £50,000 and £60,000 had been distributed by the Institution, and there were upwards of 150 pensioners on the list, which alone proved its usefulness. The past year was a marked one in the annals of the Institution, inasmuch as the report showed an increase in the income and a decrease in the expenditure. (Hear, hear.) He thought it was a very excellent feature to assist those who had made an endeavour to help themselves. The funds, he observed, were widely and economically distributed. He had had some experience with benevolent societies, and some he knew were organised for individuals and highly paid officials. Happily this was not the case with the Gardeners' Royal Benevolent Institution. This was managed on the most economical lines, and deserved the support and sympathy of all who took an interest in horticulture. A gardener's life, he thought, was a happy one, and, as a rule, his work pleasant; but withal it was especially desired that some provision should be made for a rainy day, as none of us knew when a day of adversity might come. It was impossible, however, for many working gardeners to make an adequate provision for old age and infirmities. He was much struck with the casualties which brought the candidates upon the list, and although fourteen pensioners had that day been elected, it was a sad fact that twenty-five deserving cases had to be turned away. All interested in the Institution should remember this and endeavour to render the Committee all possible aid, so that there may be no disappointed candidates. There were, he was glad to see, many friends of the Institution among the City companies, and perhaps he might be of further assistance in that respect. (Hear, hear.) Many others he might individualise, such, for instance, as the worthy Treasurer, who celebrated his silver wedding by subscribing £500 to the Institution; and Mr. Sherwood, who had likewise given most liberally. These were friends indeed, and so long as the Institution had such he had no doubt as to its continued prosperity. (Applause.)

Mr. N. N. Sherwood briefly responded, and said that his only regret, after such an excellent speech from the Chairman, was that there were no subscriptions collected that night. He was glad to say that the Institution is in a fairly flourishing condition, but he wished they had been able to place the whole of the candidates on the pension list. As the Chairman had said, the gardener's life, up to a certain stage, was a happy one; but there was a dark side to the picture. Gardeners had to be out in all weathers, and for the work required of them no men were so poorly paid. It was impossible for them alone to support the Institution themselves, and therefore he trusted that all who could would render assistance. There was one friend absent that night who might be regarded as the Father of the Institution. He referred to Mr. John Lee, who, he was sorry to say, was suffering from a severe illness, and he was sure that all would earnestly hope for his speedy recovery.

Mr. H. J. Veitch gave "The Chairman," and remarked that much depended upon securing the services and aid of such gentlemen. He felt confident there was a bright and happy future for horticulture. He was sure also that Mr. Foster, as a member of the House of Commons, would watch the interests of the Institution and horticulture generally.

The Chairman, in responding, said that he should never forget the Institution, and intended to become a life member.

Mr. Nutting proposed "The Secretary," to which Mr. G. J. Ingram briefly responded.

With the aid of a selection of music all present spent a most enjoyable evening.

#### THE WEATHER AND THE BIRDS.

THERE are certainly not a few birds that we outdoor gardeners wish further. We have sent the sparrow to Australia, unfortunately without losing him altogether, and there are some other birds which those of us who pride ourselves on the size of our Strawberries, or the lusciousness of some of our other fruits, would probably rejoice to hear were exterminated. The rigours of a winter such as we have been enjoying (?) no doubt end the lives of hundreds, but the summer sees the generality of these feathered bipeds as numerous and active as ever, and many of us vowing vengeance on them. But in such a winter their miserable puffed out condition, the melancholy, woe-begone appearance they assume touches most of us, and we put off the execution of our murderous thoughts. Generally, too, the Press, urged on by correspondents, pleads their cause, and "Remember the poor birds" forms the text for long dissertations. In this world we must take the evil with the good, and recognising that many birds are most useful to us gardeners, we feed our friends and let our enemies share the spoils.

Personally until this winter the time to watch the vagaries of the feathered race has been denied to me, but now I have been conveniently placed and could devote a little leisure to that watching, which has proved most interesting, so much so that I promise amusement to those who choose to keep an eye on them.

Firstly I must say that I am now well situated. My windows reach to the ground and open on to a large stone step, and so down to the garden. The few crumbs from the breakfast table have been regularly thrown out here, but during this awful, and I do not use the word in its slang meaning, in this awful weather, they have been liberally supplied, and very rapidly the viands disappeared. Have they any means of communication? and if they have do they set us an example of sharing with others the goods provided for them? I cannot answer, but whatever be the cause the numbers of the suppliants increase, so too do the varieties. At first in the warmer times it was only the ubiquitous sparrow, the laziest of all birds as my experience goes, which visited us. The cock robins would take a crumb, thank you, and be off. As the weather became more severe these became regular customers, and the hedge sparrows joined the party. These were followed by two chaffinches, later a third appeared. Then a black-pied water wagtail has turned up. This specimen was evidently suffering and looked pitiable, and I fear has gone over to the majority, for the last day or two it has not joined the group. With the increase of cold a mutton chop bone was put out, and this proved an unfailing source of quarrels, and has been pulled about hither and thither over the lawn. Thrushes and blackbirds ran about the lawn, but if they approached the window it was only occasionally. Then seeing the gusto with which the chop bone had been received we went a step farther. The bones of the beef sirloin were placed some 8 or 10 feet from the window. Stuck up on end they acted as scarecrows for many hours, the birds evidently taking them for a trap of some kind. We then had the bones moved on to the step outside the window, and fully expected the robins would soon attack them; but no, they took the crumbs around it, but avoided the bones. So far as we could make out either the little blue tit or the coal tit were the first to tackle the joint, and the dainty little gems plied their beaks well, returning again and again to the attack. Later a long-tailed tit joined the party. The tits were followed by one of the thrushes. One of these having at last discovered what the bone meant has remained its most constant companion. This bird is a perfect glutton. It may be good for the human stomach to rest a while after food. It does not seem necessary with the thrush, if I may judge from this specimen, but for the interference of a hen blackbird, which seems to be a perfect virago, and to spend her time in driving away any bird that seemed to be at all enjoying life. But for this the thrush might possibly have been frozen to the bone, and on several evenings she seemed to me as if she meant to roost upon it. Certainly she would keep pegging away at the frozen joint, standing on it, lifting it and herself as well long after all the other birds had gone to roost.

The thrush is certainly one of if not the earliest bird, except perhaps the lark, in singing his morning chant; but, judging from our friend here, he is also the latest in going to rest. It is no use preaching to him, or we might tell him that he is "burning the candle at both ends." The blackbird now and then would try the bone, but never in the same way as the thrush. One blackbird would pick a large piece of the soft half frozen sop out of the plate, and with an effort be nearly upset and drop the morsel, which was at once pounced upon by half a dozen sparrows and carried off. Never venturing near the window a pair of wrens are occasionally seen, apparently being busy insect-searching over the bark of the trees.

By far the most cheeky and impudent, and apparently least suffering, are the tits. These were the most fearless; would stand up for themselves, and not be driven off by chaffinch or hedge sparrow—indeed, without being quarrelsome, they appear to me far more plucky than the robins, determined to make the best of matters, and so giving us gardening folk an example of good temper and perseverance under the difficulties that frost and snow bring upon us. The robins now and then stand on the step and warble out their thanks, so the ladies seem to think; but I catch a rather defiant tone in it, and am rather disposed to think that they see a rival; certainly they are the most impudent after our little friends, the tits.

As regards fear of man, the thrush was far and away the least timid; he would continue undisturbed, working away at his beloved bone with our watching him only a yard between us. Next to the thrush the hedge sparrows and robins stood their ground the best. In

the early morning, if all the previous day's food had been disposed of, the smaller birds unceremoniously tapped the window, much to the astonishment of the housemaid, who nevertheless understood the call and supplied the wants.—Y. B. A. Z.

#### HARDY FRUIT GARDEN.

**Pruning Outdoor Vines.**—During favourable weather the first opportunity ought to be taken to prune and regulate the growths of outdoor Vines. This work can often be done when it is impossible to approach fruit trees in the open owing to the state of the ground. Vines on walls are usually situated in warm sheltered positions, and even if the ground around is covered with snow, but the temperature ranges above freezing point, there is little difficulty in carrying out all the necessary details.

**Treatment of the Old Branches.**—No Vine ought to be allowed to retain a large number of old, thick, gnarled branches, as they are useless to produce fine bunches, but invariably give samples of fruit lacking in quality and deficient in flavour. Such branches as these should be cut out, a few every year, young growths being trained to take their place. Where some forethought has not been exercised to encourage suitable young canes for taking the place of old branches it is not advisable to severely thin out the latter, but a start may be made, taking one or two of the oldest and worst placed out first, severing them neatly with a saw near the base of the plant.

**Treatment of Young Canes and Lateral Growth.**—Strong young canes that may be intended to replace old branches must be cut well back if they have grown very long, to firm, bold buds on hard, well-ripened wood. It is only buds of this kind which produce strong growth, an essential when extension is needed, as well as for securing serviceable bunches of fruit. The lateral shoots on older canes and branches ought in most cases to be pruned back to a few good buds at their base. If suitable buds, however, are not situated low enough they must be selected at longer distances at the risk of causing the formation of long spurs. This can be partly avoided by retaining the growth from a lower bud in addition, cutting off any fruit bunches that show on it, but encouraging it to grow strongly and produce large leaves. Bold buds will thus be built up at shorter distances from the main stem, the shoots being shortened at the next winter's pruning to them.

**Cleansing the Rods.**—It is not generally the case that outdoor Vines are much troubled with insects, especially if well managed. But, of course, through neglect and inferior cultivation they are liable to attacks of red spider, thrips, and mealy bug—the same as Vines under glass. If any signs of insect infestations are apparent, the whole surfaces of the Vines should be thoroughly well washed with softsoap, 4 ozs. to the gallon, dissolved in boiling water. In bad cases they may have this preliminary washing first, then receive a dressing with the soap solution, to which a wineglassful of petroleum has been thoroughly worked-in, applying it to the wood with a brush, with which every crevice in the bark may be penetrated. All loose bark should be removed previous to dressing the Vines.

**Cobs and Filberts.**—A plantation of Nuts is a welcome addition to the hardy fruit garden, and if trees are not planted between standard Apples and Pears a piece of ground might be set apart for them. They enjoy liberal treatment, and pay for it by producing good crops. Like the majority of fruit trees, the chief essential in their cultivation is a sufficiency of light and air to every part of the trees. This can only be accomplished by planting trees in the first instance wide enough apart, from 9 to 12 feet being a good distance.

**Planting.**—The soil must be well prepared by deep digging and manuring as soon in the winter as possible. Strong suckers are the best for planting, as from these bushes can be readily trained into the desired shape. Planting may be done in dry weather in February or March. Choose suckers with a single stem possessing a number of fibrous roots, which will hasten the establishment of the plants.

**Trained Bushes.**—Whatever mode of growth is ultimately encouraged it is imperative that a start be made by cutting back the tall sucker stem to within 15 inches of the ground. The shoots which start from this shortened single stem may be reduced to three of the strongest. These, again, must be shortened back the following winter to within a few inches of the main stem. From the next breaks sufficient shoots must be selected to form the bush, each shoot being trained outwards at equal distances apart, the whole of them forming a circle with a clear centre. While the process of shaping the trees is going on the leading growths are each year reduced to about a foot in length at the winter pruning until a height of 6 feet is reached, no further extension being then allowed for medium-sized bushes. At each winter pruning the current year's shoots or side growths are shortened back, as well as the old bearing wood, the slender growths or spray which bear the catkins being left alone.

**Unpruned Bushes.**—Larger and more prolific bushes can be produced after the trees have obtained the requisite number of branches by avoiding the annual pruning altogether. The branches, however, must be trained thinly in the first instance, and whenever any disposition to

overcrowding is shown remove the superfluous portions. With every facility for extension and plenty of light and air among the branches a height of 20 feet will be reached by the bushes and half that distance in diameter attained. Such bushes or trees are immensely prolific. They are suitable for some gardens but not all, the dwarfier restricted trees being better adapted where space is limited, also where Nuts are grown between the lines of other fruit trees.

**Varieties.**—Cosford Cob is large and early. The Red and White Filberts are good, and should be included, while the Kentish Cob, one of the best and most prolific, will produce the latest supplies.

**General Pruning.**—Proceed as the weather permits with all pruning of fruit trees in open quarters, as well as pruning, nailing, and cleansing of wall trees, Apples, Pears, Plums, and Cherries needing attention first, Peaches, Nectarines, and Apricots having had the old bearing wood removed, being in no hurry to be closely secured to warm walls. They are, in fact, better a distance away, except during the prevalence of very sharp frosts, when the walls afford protection. Well ripened wood, however, is not easily injured by frost.

**Birds and Fruit Buds.**—In situations where troublesome birds are numerous and attacks on fruit buds expected, dredge a mixture of soot and lime, the latter predominating, over the buds, which will act as a deterrent and do no harm to the buds or trees. Gooseberries usually need most attention, especially if pruning is completed.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest House.*—Continue the instructions given in our last calendar under this heading as regards setting the fruit, and when that is effected an occasional syringing on fine afternoons will assist the fruit to throw off the remains of the blossoms. Avoid, however, regular and heavy syringings at this stage, as the foliage is tender and evaporation not great. Sufficient moisture will be maintained on dull days by damping the path and border in the morning and afternoon; if syringing is necessary to cleanse the trees of insects at such time, let it be done early in the day, so that the foliage can become dry before night. When the fruits swell and are too thickly placed, remove a few of the smallest and those on the under side of the branches, but do not thin too severely or fitfully, removing a few at a time. Disbudding also must be done cautiously with early forced trees, taking a few of the foreright shoots—upper or lower side of the trellis—first, then proceed in a similar manner with the others, only a few being removed at a time, commencing on the most forward parts. Care must be taken to leave a growth at the base of the present bearing shoot to supply its place another season, and another must be left on a level with or above the fruit to draw the sap to the fruit; the upper shoot having its point pinched off at the third leaf, unless it be necessary for the extension of the trees, when it should be trained in its full length.

If the trees are extending the shoots necessary for their formation must be trained 12 to 15 inches apart. Instead of disbudding extensions—shoots not required for laying-in to form the bearing wood of next—pinch the superfluous shoots at the third leaf, and to one afterwards, then they will form spurs. The bearing shoots on extension-trained trees should be about 15 inches apart, all being given space so that the foliage is fully exposed to light and air, and room for training in a successional shoot another year. Overcrowding is prejudicial to the crop, and does not favour the succeeding one, therefore leave only the shoots essential to the proper furnishing of the trees, and those required to bring the current fruit to perfection and provide for next year's crop. If fermenting materials have been used inside the house, still continue to turn and add fresh but properly sweetened, as rank manure will give out ammonia too powerfully, and the foliage will be injured, and the young fruit may drop.

Evaporation troughs charged with liquid manure are useful not only in preventing the atmosphere becoming too dry in the immediate vicinity of the pipes, but in giving off ammonia. Failing fermenting materials or evaporation troughs, damp the house in the afternoon after the foliage becomes dry with liquid manure, the drainings of stables or cow houses being suitable, not using the liquid too strong; if neat, dilute with six times the bulk of water. Inside borders will need attention for watering, making an examination, and when found necessary afford a thorough supply. Weakly trees may be assisted to swell their fruit in the early stages by a supply of liquid manure, but it must be given to trees having a tendency to exuberance with great care, whilst healthy trees will swell their fruit much better by judicious feeding from the start. Always apply water or liquid manure at or slightly in advance of the temperature of the house.

If aphides appear fumigate moderately on two or three consecutive evenings, but very carefully, as an overdose skeletonises the leaves, and may cause the fruit to fall; or syringe with a solution of softsoap, 2 ozs. to a gallon of water, and half pint of tobacco juice being added, it is good against aphides, red spider, and mildew. The following may also be used:—Steep 4 ozs. quassia chips in a gallon of water overnight, boil a quarter of an hour, and add 4 ozs. of softsoap to it as it cools, stirring and straining. This may be applied to shoots infested with brown aphids with a brush, so as to dislodge the pests; and, adding a gallon of water to the mixture, the trees may be syringed with it, syringing the following day with clear water. Mildew is seldom troublesome in forced houses, because the syringing washes off the spores of the fungus; but if it should appear dust promptly with flowers of sulphur. Ventilate carefully in clear frosty weather, avoiding cold draughts, as these cripple the foliage, and may cause the fruit to fall.

**Trees Started at the New Year.**—When the trees started early in January are swelling their buds and the flowers showing colour, the

night temperature may be advanced to 45° to 50°, and 50° to 55° in the daytime by artificial means, and 60° to 65° from sun heat, ventilating freely above 55°, and leave a little constantly at the top of the house. In cold weather 5° less all round is better for the trees. Cease syringing the trees, but damp the floor occasionally, so as to maintain a genial condition of the atmosphere. If the blossoms are very numerous remove those on the under side or at the back of the trellis by drawing the hand reverse way of the growths.

**Trees to Afford Ripe Fruit Early in July.**—The house containing such varieties as Royal George and Grosse Mignonne must now be closed, syringing the trees occasionally, but only using fire heat to prevent the temperature falling to freezing during the night. If, however, the trees have not been forced before, the heat may be turned on in the morning so as to raise and maintain a temperature of 45° to 50° through the day, above which ventilate freely, not allowing an advance to 65° from sun heat without full ventilation, and at night fire heat should only be used to exclude frost. This will induce gentle activity in the trees, and is better than bringing them on rapidly by a higher temperature. Trees previously forced will start without any stimulus at the usual time.

**Late Houses.**—Notwithstanding the severe weather the buds of the trees in houses with fixed roofs are swelling fast, and must be freely ventilated in bright weather so as to retard them as much as possible, not omitting to water inside borders if they show the least tendency to dryness. Those from which the roof lights have been removed are still quite dormant in the buds, and they adhere firmly to the wood, whilst the trees under fixed roofs and frost excluded for the sake of plants are not only bursting some buds but casting a majority of the blossom buds. The borders of the houses from which the roof lights have been removed have been well moistened through to the drainage, and will not need a supply of water until the fruit is swelling.

**Melons.**—When the seedlings show the second rough leaf they may be planted in the hillocks or ridges, or if that is inconvenient the plants should be transferred to pots a couple of inches larger in diameter, as those cramped at the roots in their early stages seldom make a good growth afterwards. Plants intended for pits and frames should have their points pinched out at the second rough leaf, and may be planted in their fruiting beds as soon as they require more room at the roots. The soil should be had under cover a few days to dry, be chopped moderately small, and turned twice to become thoroughly mixed if other material are used besides turfy loam. That taken 3 inches deep off a pasture rather heavy in texture, cut and stacked in the previous autumn, and containing a fair amount of grit, grows capital Melons. If the loam is rather close add about a sixth of old mortar rubbish, if poor add a fourth of thoroughly decomposed manure, and free from worms, and in any case a pint of soot may be mixed with every bushel of compost. Cleanse the house or pit thoroughly, removing every particle of the old beds, scalding every part of the house with hot water, washing the woodwork with softsoap, hot water, and a brush, the glass, inside and out, with clear water, and limewash the walls. See that the rubble about the hot-water pipes is clear, or if the bottom heat is supplied by hot-water pipes in a chamber see that the surplus water can pass away freely. Make a ridge of soil where the plants are to be put out, about 2 feet wide at the base, and 1 foot wide at top, and 10 to 12 inches deep. When it gets warmed through a plant may be put out in the centre of each light, say 3 feet 6 inches to 4 feet apart if the plants are to be treated on the alternate system, and between these other plants to afford one or two fruit each for an early supply, otherwise allow 30 to 36 inches between the plants. Press the soil firmly around each plant, having the plants and soil moist, so as not to occasion the need of water at planting. If there is reason to apprehend the attacks of slugs draw a circle of quicklime or dry soot round each plant, and place a little moistened bran on slates to attract the pests, and look for them after dark with the lantern. Woodlice will generally hide between two pieces of old boards laid one on the other, so that the insects can just get between, especially if a little oatmeal is placed on the lowest board, and these can be removed in the morning, and the contents scattered before fowls. Crickets and cockroaches sometimes prey on young Melon and Cucumber plants, for which there is, perhaps, nothing better than phosphor paste spread on pieces of bread or slates, but this is a dangerous poison and must be carefully used. When the plants are out in pits a hillcock should be made in the centre of each light by putting in a barrowful of soil, flattening the top, which should be about 9 inches from the glass or not more than 1 foot, the depth of soil in the centre of the hillcock being about 10 inches.

**Temperature for Melons.**—Maintain a steady bottom heat of 80° to 85°, or, if from hot-water pipes, 75° to 80°, as when the heat is from fermenting materials it must necessarily be high at the commencement, and the day temperature 70° to 75° by artificial means, advancing 5° to 10° from sun heat, and as much more after closing; the night temperature 65° to 70°.

#### THE FLOWER GARDEN.

**Sowing Tuberous Begonia Seed.**—There are two good reasons why the seed of Tuberous Begonias should be sown early. One is because such very small seed always germinates more surely before the sunshine has gained greatly in power, and the other is that unless the plants are raised early in the year they will not have attained a serviceable size at bedding-out time. Most seedsmen now supply reliable strains of Begonias for bedding out. Those with flowers borne on erect stems are rightly preferred, the drooping varieties being better adapted for vases, window boxes, and hanging baskets. If proper precautions are taken every seed should germinate, a small packet yielding 200

or 300 plants, or perhaps more, and these may be had each 4 inches or more through by the first week in June, making a good show before the summer is far advanced. Prepare pans, in preference to pots, by carefully draining, covering the crocks with moss, on this placing some coarse soil, and finish off with about 2 inches of a very fine mixture of loam, and either leaf soil or peat in equal parts with a little sand added. The soil used ought to be perfectly free of worms and insects generally, even if this necessitates well roasting it over a fire. Make the surface perfectly level and firm, and then well moisten it either by partly immersing in water or else by gentle overhead waterings. This to be done at least six hours prior to sowing the seed. Do not surface over with silver sand, as the latter does not afford the tiny seedlings, newly germinated, any root-hold, and numbers of them perish accordingly. Sow the seed as carefully and thinly as possible, patches of seedlings being liable to damp off wholesale. Hot-beds, unless perfectly free of worms, are bad places, though most often selected, for Begonia raising. An upheaval of any kind or souring of the soil is likely to prove fatal to many seedlings, and the safest and best place for the pans are shelves suspended, not far from the glass, in a forcing house or plant stove. Cover them closely with squares of glass, and the latter with a good thickness of moss or brown paper. Also protect the pans from sunshine. Never once must the soil in the pans be allowed to become dry, nor should they be watered through a can. A short period of dryness would prove fatal to the sprouting seeds, and however gently water may be applied from overhead, the chances are this would have the effect of dislodging and spoiling many of the seeds or tiny seedlings. Whenever the soil is approaching dryness immerse the pans in a bucket or tank of tepid water just deep enough for the moisture to soak upwards without at the time actually reaching the surface. The seeds may germinate in a fortnight or so, the time being largely determined by its age, and directly the tiny seed leaves are detected admit light gradually, and also slightly block up the glasses, taking good care though that no sunshine shall reach the Begonias. By way of a preventive of damping either wipe or turn the glasses every morning. The seedlings will require to be pricked out long before they are large enough to be picked up with the finger and thumb.

**Dwarf Lobelias.**—When a good strain is procured seedlings of these are as compact, floriferous, and true to name as are cutting-raised plants of named varieties. The seed should be sown early, and much as advised in the case of Tuberous Begonias, and then there will be less likelihood of failure than there would be if sown a month or six weeks later on. If the seedlings are duly pricked out and grown on without receiving a severe check extra strong stocky plants will be ready for bedding out late in May.

#### PLANT HOUSES.

**Allamandas.**—Where a temperature of 65° can be maintained plants that have enjoyed seven or eight weeks' rest may be started into growth. If grown in pots turn them out and reduce the old balls by at least one-third. If very dry soak the plants in tepid water, and allow them to drain thoroughly before potting. Drain the pots well, and use for a compost good fibry loam, one-seventh of decayed manure, and a little sand if the loam is heavy. Press the soil firmly into the pots. The plants should be syringed once or twice daily. Very little water, if any, will be needed at their roots before they break into growth. Plants that are planted out may have a good portion of the surface soil removed and replaced with rich compost, one-third of manure instead of one-seventh may be added. Young plants grown from cuttings last year need not be unduly rested, and if the wood has been well ripened shorten back the shoots, say to 1 yard each, and if the plants were early induced to make two they may, after placing them in larger pots, be laid horizontally at the eave of the house, when they will break from nearly every eye and cover a good space of roof this year.

**Ixoras.**—Cut back the points of the shoots of plants that have been rested if necessary. It is a good plan to shorten back the whole, then they break evenly, and the majority of the trusses expand at one time. Before placing these in a temperature of 65° to 70° see that they are free from thrip and mealy bug. If the former exists wash the plants over a tank thoroughly with a solution of tobacco water; if the latter, syringe them with petroleum, 1 oz. to the gallon. If possible give these plants gentle bottom heat, they will then start much more freely into growth. Do not over-water or syringe them. Once they have broken into growth and the roots are fairly active, repot any that need more root room. In repotting do not disturb the old ball further than is necessary to remove the drainage. Use a compost of good peat and sand, or equal parts of loam and peat. After potting the most careful watering is needed. Ixoras in small pots should be grown on a much larger scale for purposes of decoration.

**Stephanotis floribunda.**—Plants that had their wood well ripened in a temperature of 55°, and have since been kept moderately dry at their roots, will soon start into growth if introduced with Allamandas or Ixoras. Before doing so, however, wash the plants thoroughly with a solution of petroleum and water to remove any trace of bug that may remain upon them. Green unripe ends may be removed, and the plants if grown in pots should be top-dressed with decayed manure. These plants do well for several years in the same pots if they are liberally fed during the season of growth. A little artificial manure should be applied to the surface once a fortnight. Be careful not to give too much water at their roots at first, for after having been kept dry they are liable to decay. Syringe the foliage once or twice daily according to the state of the weather.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### KNOWLEDGE ON BEES.

It does not follow that the person with most knowledge on bees and their habits is always the most successful in securing the most and the best honey. On the contrary, it sometimes happens that things are reversed, and the novice, through favouring local circumstances, has the best of it. The experienced bee-master will, however, as a rule, far outstrip the inexperienced one. Although it is not entirely essential for bee-keepers to know all about the natural history of the bee, it is desirable for them and naturalists to know as much as possible. In order to assist both in the study, I will explain several things on which there is a wide divergence of opinion.

### EGG TRANSFERENCE AND DEPOSITION.

It has been frequently asserted that bees transfer eggs to queen and other cells, and that the queen regnant deposits eggs in partly made queen cells. In hundreds of examinations and experiments I never found either. This past summer, in order to test the matter more thoroughly, I made many crucial tests, but not in one single instance did I detect an egg transferred to any cell from where the queen deposited them. I have witnessed very often eggs deposited in partly built queen cells, but in every instance these were eggs from fertile workers, or unfertilised ones deposited by the queen regnant, inasmuch as they always developed into drones.

Were we to believe the theory that bees transfer eggs to queen cells or that queens deposit them there, then, on the other hand, we should be compelled to believe that bees had various ways of accomplishing their ends. When a hive is deprived of its queen the bees raise queens upon worker cells containing eggs or larvæ only, whether there be queen cells or not. I have never observed an egg transferred. I raised thousands of queens during the past summer 5 inches above the brood nest, and there never was an egg removed to it.

Notwithstanding all that has been asserted to the contrary, the student may dismiss from his mind the wild idea that bees either transfer eggs or that queens deposit them in queen cells. If there has ever been a reliable case it is exceptional, and but proves the rule, that the queen deposits the eggs where they are to hatch and be nursed into perfect insects, whether they be queen, worker, or drone.

### A BEE-KILLING QUEEN.

In 1863 an imported Italian queen was introduced to a hive of common bees, which she attacked and killed over a thousand of them, and since then we have had others with a similar spirit. Such refractory queens are, I believe, the direct cause of their own death, and it is that fighting spirit in both bees and queens that we have to guard against and get rid of before we can depend upon a successful union. Our safety queening cage enables us to discern at a glance when it is safe to let them remain together.—A LANARKSHIRE BEE-KEEPER.

### FENNEL AND BEES.

For two or three years past I have noticed in a neighbouring garden where several plants of Fennel flower and seed every year, that a number of bees are invariably at work amongst the flowers, presumably for the pollen for the cell formation in their hives. I am not a bee-keeper, so am not at all learned in bee lore, and it may be a well-known fact that Fennel is cultivated by bee-keepers; at all events I mention the circumstance as one coming under my notice, and there was no mistake about the bees being very partial to these raids upon the flowers of the herb Fennel.—W. D.

### THE LANARKSHIRE HIVE.

I HAVE tried this hive, and find all that is claimed for it by our friend "A. L. B. K." is quite true. Although a large hive it is by no means clumsy, but is light and portable; the ventilating floor I consider is perfect in every way. Those who move their bees to the Heather or Clover districts could not do better than adopt this hive. Some time ago three members of the Goole Bee-keepers' Association paid me a visit, and they were so pleased with the Lanarkshire hive that they have decided to use it, so the standard hive and it will be tested side by side next season. My best comb honey in sections last season, and for which I obtained two first prizes, were taken from the Lanarkshire hives.

### SOILED HONEYCOMB.

I have come to the conclusion if we want honeycomb of spotless whiteness we must follow the advice which for many years

has been given in the pages of this Journal by "A. L. B. K." We modern bee-keepers make a great mistake in opening all the crown of the hive when the supers are put on, and we have in consequence discoloured honeycomb. This might be prevented by admitting the bees by the sides of the hive only.

### THE SEASON OF 1892.

The past season was disappointing to many bee-keepers. In this district (Howden) very little honey has been gathered; in some cases the in-gathering will not tide the bees over the winter, and feeding had to be done to keep them alive. But personally I do not grumble; most of my hives did not swarm, and being strong in bees I got a good supply. Non-swarving hives with me have done the best, in some cases giving plenty of stores to last till the spring, while swarms and stocks that swarmed had to be fed. Strong hives pay the best.—A HOWDENSHERE BEE-KEEPER.

### TRADE CATALOGUES RECEIVED.

T. S. Ware, Hale Farm Nurseries, Tottenham.—*Flower and Vegetable Seeds, Begonias, Lilies and Miscellaneous Bulbs, Chrysanthemums, and Dahlias.*

Popes & Sons, King's Norton, Birmingham.—*Seed Catalogue.*

C. R. Shilling, Winchfield, Hants.—*Vegetable and Flower Seeds.*

W. Bull, King's Road, Chelsea, S.W.—*Flower and Vegetable Seeds.*

W. Drummond & Sons, Dublin.—*Garden Seeds.*

W. Piercy, 89, Beadnell Road, Forest Hill, S.E.—*Early and Semi-early Chrysanthemums.*

Fisher, Son, & Sibray, Handsworth Nurseries, Sheffield.—*Kitchen Garden and Flower Seeds.*

W. K. Woodcock, Barkby Road Nurseries, Syston, Leicester.—*Chrysanthemums.*

J. R. Pearson & Sons, Chilwell Nurseries, Nottingham.—*Garden Seeds, Sundries, &c.*

Peter Henderson & Co., New York, U.S.A.—*Manual of Everything for the Garden.*

F. C. Heinemann.—*Flower and Vegetable Seeds.*

Henry Eckford, Wem, Salop.—*Sweet Peas, Vegetable, and Flower Seeds.*

Cunningham & Wythe, West Mill Street, Glasgow.—*Garden Seeds.*

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

"The Orchid Review" (T. C.).—This new periodical is published by Messrs. West, Newman, & Co., 54, Hatton Garden, London, E.C. As we have already notified, its price is 1s., and it is to be issued monthly.

Corrugated Zinc for Plant Stages (York).—It is extensively used for broad flat stages, and covered with gravel or broken shell answers admirably. You can let it slope a little if you wish for carrying off superfluous water, and level the surface with gravel for the pots to stand on.

Double Primula (W. J.).—The spike is decidedly more robust in character than those of the old double white usually are and the flowers tinted. We can quite understand its being regarded as a useful variety, but as you have no idea how it came into your possession we can scarcely be expected to solve the problem. The Apples cannot be named this week if at all, but they shall be carefully examined.

Lily of the Valley (A. B.).—If the crowns have been exposed to frost they will start freely into growth. If wanted as sharp as possible they should be plunged in brisk bottom heat, covering the crowns from light by the aid of cocoa-nut fibre refuse, say one inch below the surface, of the bed and allow them to grow through. As you have not the convenience of bottom heat plunge the crowns into boxes and stand them on the hot-water pipes.

Forcing Lilacs (F. D.).—These will come forward if placed in brisk heat, especially if the plants have been exposed to the frosts we have

## WINTER PRUNING.

ALTHOUGH much of the pruning which was formerly done in the winter is now performed during the summer and autumn months, still there is a considerable amount which must from necessity rather than choice be carried out in winter. The admirable instructions given in the *Journal of Horticulture* as to the importance of thinning out the branches of Apples, Pears, and Plums while the leaves were yet on them has no doubt been acted upon by large numbers of readers. Many others who would if possible have followed the same course were compelled to let the work stand over for a time on account of still more pressing matters. With labour kept down to a very low point, as it now is in many gardens, some things must perforce be put off at certain seasons, so as to equalise the labour throughout the year as much as possible. This is especially the case where arrears of pruning have accumulated. Where numbers of large trees present a thicket of growth it is not always practicable to get the whole of the work of thinning done at one time. When, however, a proper system is once established and persevered in, there is some prospect of being able in the future to carry out the work at the most suitable time. Strenuous efforts should, however, be made to give young trees timely attention, so that they may not be permanently injured by early neglect.

Those who have fruit trees of bush, standard, or pyramidal form should lose no time in giving them the necessary thinning, taking as much as possible advantage of comparatively mild weather, for not only is the work performed with greater expedition then, but the cuts made heal much quicker than they do when sharp frosts prevail. Many old orchard trees to be dealt with present a perfect network of branches, and the pruning in such cases requires to be done with great care, otherwise the prospect for next year's crop will not be promising. Trees which answer to the above description should not in one season be thinned too severely, for it must be borne in mind that when left to themselves such trees bear fruit only on the outside, and if the branches were at once thinned severely enough to leave them as far apart as those on trees well managed from the first, there would be an unnecessary waste of the good fruiting wood already made without a corresponding advantage being obtained in the shape of young growth, which takes time to bring to a fruitful state.

All dead branches, and those which show signs of being stunted, should first be cut out; next remove such cross shoots as can readily be dispensed with, but as it often happens that some cross shoots have thoroughly good wood well studded with blossom buds care should be taken to leave such shoots, even though they are not altogether well placed, till younger and better placed examples have been obtained. Trees may in this way be gradually thinned and brought to a satisfactory condition without sacrificing the greater part of one season's crop. I have seen trees the branches of which were so severely thinned at one time that there was no prospect of obtaining anything like a fair crop of fruit from them for a couple of seasons. Moderation seems to me to be the best in all things, and when Nature has been allowed to follow her own course for years Art should step in and gently guide her, instead of attempting to reverse at one stroke the order of her ways.

Bush and pyramid Apples and Pears in gardens generally are, as far as my observations go, much more productive than they

were when I began my gardening career. I can call to mind numbers which always presented a neat trim appearance, but never carried a good crop of fruit. The use of dwarfing stocks and the practice of root-pruning, where the space devoted to trees is limited, have doubtless done much to bring about this change. But the practice of thinning the shoots freely and shortening but little, after the foundation of the tree has been laid, has, I think, produced the most marked change of all. Numerous instances have come under my notice in which trees, even large standards, had for years been spurred back on the espalier principle with very unsatisfactory results, have by allowing the growths to go unshortened been changed from barren, useless stumps to vigorous fruitful trees. I think even now there is a general tendency to err on the side of crowding. Many who now practise the right system on the young trees which are growing into fruitfulness would do well to keep the branches still thinner.

Apple and Pear trees trained as cordons, or fan-shaped, will require but little attention now if the summer pruning has been well attended to. Side shoots which were then stopped at five or six leaves should now be shortened back two or three eyes, the weaker ones being of course cut back the closest. Young trees which have still a considerable amount of room for extension, if they have already formed the requisite number of branches, should not be shortened back except in the case of unripened wood or weak shoots; the latter should in most instances be cut back to a good bud, and the former to where the wood is well ripened. If, however, the main branches are disposed 15 inches apart there is but little likelihood of unripe wood being produced. Plums show a great tendency to develop a number of short jointed shoots from 3 to 6 inches in length. I make a practice of leaving some of the most promising of these their full length, and after they have fruited cut them back close to the main stem, this being done as soon as the fruit is gathered.

Perhaps the most difficult type of wall trees to deal satisfactorily with are old examples of either Apples, Pears, or Plums, which, through having been constantly spurred back closely year after year, have become a mass of unsightly spurs. Quite half of these may, in the majority of instances, be cut clean away, and those left shortened back to healthy buds. Old Pear trees which have been confined within the same space for years may be greatly invigorated by shortening back the main branches 2 or 3 feet, and filling the space as soon as practicable with young shoots.

In dealing with Apricots the aim should be to have the whole of the wall space covered with shoots and spurs 6 inches apart. After the space is once covered the winter pruning consists only of cutting out enfeebled spurs and shortening back summer-pinched shoots. I have formed the opinion that if Apricots were treated on lines similar to Peaches we should hear less of branches dying wholesale, and in the future I intend to act upon that belief by laying in young shoots all over the tree in summer time, and instead of cutting out these shoots each year, as in the case of Peaches, allow them to remain two years to form fruiting spurs; then after the fruit is gathered remove a sufficient number to keep those left 6 inches apart.

Morello Cherries should have the bearing wood left as near as possible 6 inches apart all over the tree. Any shoots which have grown to within a few inches of a branch above them ought to be shortened to the next break. There is generally a tendency to overcrowd the shoots of this useful fruit; the long, thin growths produced lend themselves so admirably to mathematical training that it is not easy to resist the temptation to leave an extra shoot here and there for the sake of present effect, when it can be clearly seen the summer growth must in consequence become crowded.

Where bush fruits are not already pruned no time should be lost in doing them. Black Currants simply require the young shoots to be left from 6 to 9 inches apart all over the tree, giving

preference to moderately strong, short-jointed ones. Where the bushes are becoming too tall, remove some of the longer branches by cutting them back to young shoots near the base of the bush.

Red Currants, on the other hand, ought to have the side shoots closely spurred in, allowing the extremities of the branches to extend about 6 inches each year till the required height is reached, when they may be cut back to one joint. Where gaps occur through the removal of old or dead branches young shoots may be left a foot in length to fill the vacancy.

It is a good plan to leave the pruning of Gooseberry bushes till all other bush fruits have been done on account of the great havoc birds play among the buds. The best method to follow is to thin out the young shoots to about 6 inches apart, those which are removed being cut back to one eye. No shortening of young shoots will be required except in the case of those likely to be brought to the ground with the weight of fruit. It is also an excellent practice to leave the centre of the tree rather open. Extra fine fruits are produced by training a few trees to wires or fences and spurring the branches in closely. This, however, is not the best method to adopt for general purposes; but those who carry out this system well are justly proud of the fine results achieved.—D. W.

### BRUSSELS SPROUTS AND THEIR CULTURE.

THIS vegetable is probably the most useful of any of the other forms of culinary produce obtained from the Brassica family during the winter and early spring. It is true that where the climate is favourable Broccoli may often supersede some of the more commonplace vegetables, which I have found to be the case even in northern districts, when an unusually mild winter effected a general improvement in the ordinary routine of kitchen supply. Among winter greens during a semi-arctic period, however, with which many vegetable growers are not unfamiliar, I consider an adequate supply of moderate sized firm Sprouts to be the gardener's sheet anchor. I have known instances in which Brussels Sprouts were regarded with some indifference, coupled with a suggestion from headquarters that a smaller plantation of them might suffice for the following season. Young and inexperienced practitioners should not, however, attach undue weight to suggestions of that kind, otherwise some rigorous period in early spring, when a supply of this sometimes rejected vegetable would be eagerly accepted, may lead them to discover their mistake.

Referring briefly to the cultivation of Brussels Sprouts, I have picked fair crops of useful produce from spring sown plants raised on the open borders. These, however, were seldom so early, firm, and abundant as others from seed sown early in February under glass, then pricked off, and grown under the influence of plenty of light and air. When the seedlings are pricked out in frames the sashes should be removed on every favourable opportunity as soon as free growth is apparent, as the object of the grower should be to secure a stock of thoroughly hardy plants by the time they are ready for their places in the open quarters early in May. If for convenience they are started in boxes placed in other cool structures we afterwards turn them out to the foot of a wall or some place of shelter, where they can be afforded additional protection if necessary, and made secure from possible injury of any description by adjusting wire netting over them. Whilst thus located the plants must be regularly attended to as regards watering, and in order to prevent them being drawn up weakly, no more covering should be used than is absolutely needful to save them from the check which would result from an occasional hard frost.

Firm land is generally admitted to be more than half the secret of the success realised in the raising of fine crops of weather-proof Brussels Sprouts. While admitting this in principle I do not know that turning out the plants on ground that may not have been moved with a spade or prong for one or more years is the only method by which the proper conditions towards attaining successful results can be secured as far as soil texture is concerned. I have found that whether manure was applied or not, that a light digging of the square selected for planting out the seedlings very much facilitates the operations of weeding or hoeing afterwards and the treading of the ground, consequent on the performance of such work, ensures the necessary solidity by the time the plants are more than half developed. Speaking from personal experience the crops produced by the light digging system on loam of medium texture have been at least equally hardy and prolific as when planted on solid land.

For those who may not have the convenience for raising seedlings

under glass autumn sown plants can be obtained from market men, but according to my experience of a trial or two of these a considerable percentage of them proved "bolters." When such plants are procured let it be as early in spring as they can be had, and when they come to hand prick them out in a cold frame, or on a bed in the open border over which some contrivance can be fixed to which temporary protection may be adjusted if necessary. Soon after the plants have taken to the soil the "bolters" will show themselves, when they can be removed before the final transplanting is begun. It may not be superfluous to add the reminder, that it is indispensable to the best results in Brussels Sprout culture that the plants at all stages of their growth should have sufficient space for perfect development. Let them once be overcrowded and failure, or at least partial failure, must result from the check thus produced. Among other varieties I have grown within the last few years have been President Carnot and Craig's Favourite, the latter being of Scotch origin. Both are comparatively new sorts, and they appear to be very hardy and good croppers.—BRASSICA.

### MEALY BUG ON VINES.

WHERE vineries are largely used as plant houses during the winter mealy bug is frequently introduced, and unless very great pains are taken in getting rid of the insects the worry and annoyance is of a very pronounced character. Some gardeners are of opinion that once mealy bug is well established, in an old vinery especially, it is next to impossible to get rid of it again. With this dictum, however, I cannot agree. One of the vineries under my charge is probably among the oldest in the country, some of the Vines being also very old, their exact age being known to nobody I have yet spoken to about them. Twice have mealy bugs been introduced to these Vines, and twice have they been mastered. Some of my readers will be of opinion that I ought not to have been so remiss as to allow mealy bug to regain a foothold in a vinery when once eradicated, but when more pot plants are grown than there is good room for, and more work attempted than there is enough hands to properly meet them, something or somebody must suffer.

There are many and various ways of transmitting mealy bug to Vines, but I only know of one that can be relied upon to get rid of it again, and that is a thorough scrubbing of the woodwork, glass, walls, stages, and in particular the rods with hot water. It must be thorough, every crack and crevice being found out by the bristles of a scrubbing-brush, and unless this is done subsequent dressings of strong mixtures are of little avail. As a matter of fact I attach still less value to the latter than formerly, and I never wrote or spoke very highly of any other than gas tar mixture for Vine rods. There should be no skinning the rods, and hard scraping about the spurs. Doubtless this severe, most unnatural, though time-honoured custom, does lay bare many lurking places of insect pests, but stripping off the bark has a most injurious effect upon the Vines from which they never recover, unless indeed the rods are gradually replaced by bark-clothed younger ones. By all means roughly cleanse the rods after pruning, but remove the loose bark only, notably the scales about the spurs. Labourers should not be trusted to clean, scrub, and dress Vine rods, this important work being superintended and largely performed by those who take a more intelligent interest in their work or duties. Hot water with just enough softsoap dissolved in it to make it more penetrating and free working is an excellent insecticide. By hot water I do not mean a bucketful hot when first the work of scrubbing commences, and which quickly becomes cool, but it should be heated to not less than 130°, and kept at or near that during the whole time it is in use, frequent additions being made. It must be a very difficult crevice to get at that will protect mealy bug or other insects from a scrubbing-brush in good hands, though where these pests are well established it pays to give the rods a second good scrubbing.

As a further precaution it is advisable to also dress the rods with a mixture of clayey water, to every quart of which a half pint of cold gas tar is added. I have used much more tar than this to the quart of clayey water without apparently injuring the Vines in any way, but the experience of others does not always agree with mine, and the lesser quantity is recommended in order that no risks should be run, the more so that I attach less importance, as before stated, to any dressing. The clay-tar mixture should be kept well stirred, and of the consistency of thin paint when applied with rather stiff brushes. Avoid smothering the buds, or even surrounding them closely, with the mixture; tar recklessly used sometimes having the effect of injuring the young shoots, making them very brittle, and easy to snap off. Every crack and crevice ought to be well filled or cased over with the mixture, and against the latter what few insects escape the scrubbing brush will make little or no headway.

So very hard to get rid of are mealy bugs that there is almost certain to be a few survivals of the scrubbing and painting processes, and in order to quite clear the Vines of them a close look out must be kept during the growing season for any that do put in an appearance. Unless these few odd insects are destroyed before they have time to deposit eggs in the bark there will soon be a return of the old order of things, as they increase and spread very rapidly in the genial surrounding of a vinery. Next to the hot water scrubbing this hunting out the survivals is of the greatest importance, neglecting to follow it up being the most frequent cause of failure to wholly get rid of mealy bug from a vinery, —W. I.

## ONIONS.

BEING one of those selected to assist in judging the very remarkable display of what Mr. Deverill calls his pedigree stocks at his annual Show in September last, and as the season is now approaching when those who require such for exhibition purposes will be sowing the seed, it may not be out of place to say a little on the merits of these popular kinds.

There are four distinct Globe types, the largest and handsomest being Ailsa Craig. Twelve bulbs shown on this occasion scaled 26 lbs., but they were not so highly finished as usual, but certainly beautifully shaped bulbs. Cocoonut is a very large handsome shaped Onion, as is also Advancer, and I should not be surprised to see them to the front on some future occasion, their quality being so good. Improved Wroxtton is highly adapted for the general crop, being an excellent keeper; in fact, it keeps sound until June. I consider this Onion is invaluable for market work.

Then comes the section for large flat types, which comprise Anglo-Spanish, twelve bulbs of which were shown in fine form; weight 22 lbs., circumference 18 and 19 inches; and being so well finished were awarded the gold medal as the best dozen bulbs in the Show. This variety is the gem of this section, and those who want the true stock should ask for the latest development or Mr. Deverill's selection.

Then follows Lord Keeper with deeper flesh and runs Anglo-Spanish very close. This variety is higher in the shoulder but is not so solid in appearance. Royal Jubilee and Rousham Park Hero are wonderfully fine strains, and are at all times likely to hold their own, for I have seen the latter shown more than once when the dozen bulbs averaged 18 inches in circumference. The original Excelsior is a beautiful Onion and was shown in splendid form, but had no chance against the larger varieties named. I see by Mr. Deverill's catalogue he is offering prizes for Scotland, as he considers the northerners cannot compete with the southern growers.—G. A. J.

## PRICES OF APPLES—MANURE.

I THINK "A Yorkshireman" and "A Sussex Grower" (page 6) have overlooked the fact that the discussion of prices was not that of Apples generally, but of Domino Apples, and it was as regards this I thought sufficient time had been taken up. Still, your correspondents may congratulate themselves on having obtained very good prices. Doubtless among so many Apple growers as there are there will be some who obtain prices considerably over the average. Your correspondents may have had special opportunities for the disposal of produce in small towns locally. Here, in the midst of a large fruit growing district, we cannot get such good prices from shopkeepers in the neighbouring town as in the market, because they obtain the bulk of their fruit from cottagers, who, only having a tree or two, have not enough to send to a distance; they therefore sell it in Maidstone for what it will fetch, and usually the shops are glutted with cheap fruit. We are consequently shut up to London and more distant markets, and if I send to Yorkshire my return would be very different to that of "A Yorkshireman," because of the extra carriage, though perhaps in other ways our more southern climate would be an advantage.

Sometimes we can dispose of fruit very well to higglers, who take it to the seaside towns; but this cannot be relied upon for disposing of a large quantity. The average return home to us from London and the chief Lancashire and Yorkshire towns and elsewhere for Warner's King and other large cooking Apples was considerably less than the prices quoted by the two correspondents named above. At the end of August I sent up to Covent Garden some selected cooking Apples—that is, the

largest grade of large growing sorts—and they realised 6s. a bushel. On receiving a telegram as to the price they produced I sent off a large consignment of the same sort, but they only made 4s. a bushel on the following day. Five days later they made only 3s. 3d. per bushel, when I left off sending there. The fruit was not topped, and my mark is well known; there was only the vicissitudes of the market to account for it. But these contingencies we always have to face, and it is rarely that all can be sold at the top price. The cholera scare much reduced the price of Apples in London.

I may inform "W. P. W." that the statements I have made about manures were facts, and no amount of writing on the part of anyone who has merely a superficial knowledge of commercial fruit growing can dispose of them. I do not feel disposed to give your correspondent the details he requires about manures, as he appears to ask in a spirit that suggests a desire to find fault. In such a case discussion is of no benefit. I am glad to learn from anyone, but dislike mere wordy controversy. But for the sake of proving the reasonableness of my statement about manure I may say that those of your readers who live in this neighbourhood will readily believe it, for although the precise applications I give are not known to them, yet my carts are as well

FIG. 10.—CYPRIPEDIUM GERMINYANUM. (See page 74).

known as I am myself, and it is evident in manure alone that I have a large expenditure.

If "W. P. W." is not acquainted with the applications of manures by market gardeners and fruit growers who farm well, he has only to turn up back numbers of the *Journal* to gain information, such as 26th October and 2nd November, 1871. He should know that applications of 50 to 100 tons of manure per acre are not uncommon, and he will see from the articles I have named that the outlay for this alone in one place mentioned "generally exceeds £20 per acre," and a garden in Bermondsey sometimes has an application of manure value between £30 and £40 per acre. In the Bedfordshire district it is stated that for Onions "50 tons of dung per acre are sometimes applied, costing 8s. per ton at the railway and 10s. when spread in the field." After this my statement, which included cost of cartage and labour, reads as a very moderate one, and it is true I do not apply nearly as large quantities as the above. I consider a shovelful to each Gooseberry bush, and some for the crops in the spaces between, with a little extra for standards, supplemented by any particular artificial that may be necessary, a very good dressing; yet it does not look very much on the ground, but it works out to a large quantity per acre. I may be told that I can use artificial manures alone, but I found they worked out by analysis about the same price as dung, while more care has to be exercised in the application of heavy dressings. Besides this, stable manure supplies humus and holds moisture in dry weather, facts which are not considered by those who go in merely for analysis, but which make a considerable difference to the crops.

Several different crops, one overlapping the other and trees rising to some height above the ground, take a large amount of moisture from the soil. It is very obvious, for instance, that Apple trees 20 feet high are capable of bearing a great deal more fruit and exhaust ground much more than a thick plantation of bush Apple trees 6 feet high.

Although the amount of manure I use is considerably less than the examples I have quoted above, yet it astonishes many who do not use much of it. They are equally astonished at the amount of produce which comes from my ground. One thing I have found out by experience, and that is that it does not pay to be stingy with manure. I commenced with less—an expenditure of only about £3 per acre, but I find that larger applications pay better. Not only the quantity, but the size and quality of produce have to be considered. I trust that these few remarks may be helpful to your readers.—WALTER KRUSE.

### TUBES FOR HARDY FLOWERS.

I JUST refer to the mention made of my suggestion that the fixing of the size of tubes or holders of bunches of hardy flowers at 2 inches in diameter is in antagonism to that of Mr. Shanks, who favours an inch tube only, to point out how very small an orifice after all is that of an inch tube; indeed it does not exceed two-thirds of the square inch, because round. Half a dozen fair sized stems would fill a 2-inch diameter tube, because that, too, would be round, and not exceed 1½ inch square. I do not think for one moment that a bunch of flowers filling such a tube fairly would be too large, yet I think plenty large enough.

"S. P. H." (page 46) shows how his wordy definition of hardy flowers includes shrubs. Now I think it is the earnest desire of nearly all who appreciate ordinary hardy garden or border flowers, to exclude shrubs; indeed, shrubs being admitted, less conspicuous perennials would have poor chance very often. Of course it is imperative that some check should be put upon the free employment of varieties of the same kind or species. Many exhibit up to twelve bunches, all should be distinct kinds; above that number two varieties of any kind might be admitted, but the great aim of competition of this sort would be to popularise hardy border flowers, and to encourage the cultivation of many of the best. The grower who has fifty distinct kinds is better off than he who has ten kinds only, and five varieties of each, even though at one particular time the latter may make the largest display.—A. D.

### WHAT CONSTITUTES AN AMATEUR?

"OBSERVER," writing on page 44, states that the executive of the National Amateur Gardeners' Association had approached the Royal Horticultural Society in regard to the correct definition of an amateur with satisfactory results. I should like to learn how these satisfactory results are evidenced. It is very well known that the R.H.S.'s definition of an amateur always has been anyone not in the trade, so that gardeners constantly and chiefly competed in what are termed by courtesy amateurs' classes. In the Society's rules and regulations for exhibitors, published for the year, there is not a word that in any way gives a fresh or diverse interpretation, and yet it is an interpretation not accepted by any other society in the kingdom.

The National Rose Society has amateur classes, but it does not recognise gardeners. Practically, the gardener is nobody, and his employer is regarded as the amateur exhibitor. Perhaps the R.H.S. may take the same view, but then it is an absurd one, as in nine cases out of ten the gardener is the real competitor. Now the Auricula and Carnation Societies, whose rules are published in the R.H.S. schedule, have no distinctions; on the other hand, the Pansy Society have a definition, and directly excludes all gardeners, or even gentlemen who employ any other help but a garden labourer. Clearly we do want some national definition of what or who is an amateur, and one universally recognised. Will the Council of the R.H.S. really tackle this matter, and help to the establishment of a recognised definition?—F. R. H. S.

### CANKER IN FRUIT TREES—SOIL CONSTITUENTS.

(Continued from page 48.)

ENOUGH has been said to show that red soils are Apple producers. The stiff loam of Sussex on yellow or blue marly clay, impregnated with iron (over 6 per cent.) grows splendid Claygate Pearmain and Duck's-bill Apples. Cambridgeshire brick earth on a blue clay subsoil only needs two sorts to afford a supply of Apples—namely, Histon Favourite and Marfitt's Seedling. On the light oolitic soils over gravel or sand the latter variety cankers famously; therefore we will turn to the sandy soils.

Surrey.—Soil sandy, subsoil sand with ironstone gravel and a hard pan below; canker, all the Hawthornden race, Cellini, Ribston Pippin. Kent.—Soil thick, light, and sharp loam on ragstone brash; canker. Surrey again.—Peaty soil, subsoil gravel and wet-pan again; canker, Dumelow's Seedling and Ribston Pippin. Kent once more.—Soil light and good, clay subsoil; canker, Cox's Orange Pippin. Berkshire.—Light shallow loam, gravelly subsoil; canker, Lord Suffield, Dumelow's Seedling, and King of the Pippins when the roots get into the subsoil. Middlesex.—Light soil, canker after a wet season. The iron alias the pan, hence Keswick Codlin, Manx's Codlin, and Duchess' Favourite surface rooted are not liable to canker in such soil. In Denbighshire in light soil over gravel Apple trees canker; Pears on free stocks are nowhere finer. In Bedfordshire.—Sandy and deep; Hawthornden (old and new), Irish Peach, Blenheim Pippin, Ribston Pippin, Dumelow's Seedling, and Annie Elizabeth canker. So much for light soils that contain a low per-centage of oxide of iron.

Just a line or two about calcareous soils. Yorkshire.—Calcareous loam on magnesian limestone; canker, Lord Suffield, all the Hawthornden race, Calville, St. Sauvier, Ribston Pippin, Alfriston, Lord Burghley, and Pearson's Plate. Dorset.—Soil light and chalky, subsoil chalk; canker.

Now, in a sandy soil we get, as the result of analysis, a low percentage of oxide of iron, perhaps less than 1 per cent.; but with the other constituents fairly good, as per below:—

*Organic matter and loss on heating	...	...	2.82
Oxide of iron	...	...	0.92
Alumina	...	...	0.88
Lime...	...	...	0.18
Magnesia	...	...	0.12
Potash	...	...	0.07
Soda...	...	...	0.06
Phosphoric acid	...	...	0.10
Sulphuric acid	...	...	0.01
Insoluble silicates and sand	...	...	94.84

100.00

*Containing nitrogen	...	...	0.12
Equal to ammonia...	...	...	0.15

—("Elements of Agriculture," Fream, page 20.)

The soil corresponding to the analysis is not fit for Apples; for this reason—there is not enough alumina to hold anything in the way of manures. But if we apply a dressing of blue clay marl, 100 cartloads per acre, during frost, throwing the lumps evenly on the ground, spread regularly after a thaw, and fork or plough-in, that land is improved 50 per cent. as a manure economiser and for producing Apples. Why? Because the elements of which the sandy soil is deficient are supplied in the clay marl (too stiff as a soil)—namely, oxide of iron 5.77, alumina 5.15, carbonate of lime 19.92, magnesia 0.25, potash 0.62, soda 0.09, phosphoric acid 0.38, sulphuric acid 0.04, soluble silica 13.45 per cent.—clear gains all round of elements essential to plant nutrition.

It is similar with a calcareous soil as sandy; both are deficient of organic and inorganic substances. A clay soil may contain 7.21 per cent. of organic matter, and lose on heating, and a marly soil 10.50, but a sandy soil seldom contains 3.00, or a calcareous (chalk) soil more than that amount. The iron in chalk soil rarely exceeds 1.50 per cent., its alumina 1.75, but it will generally show better percentage of potash and phosphoric acid than a sandy soil. Notwithstanding, the chalk soil is not an Apple-producing staple.

Soils, however, are greatly influenced for production by their mechanical nature. A loose, good calcareous loam, strong enough to grow Wheat, and intermingled freely with flinty particles, may be so deficient in food that Apple trees languish in it. I was particularly struck with the appearance of an orchard the other day on this formation (chalk) in Hertfordshire. It is an ordinary orchard attached to a farm house, about two acres in extent, planted about twenty-five years ago with Apple, Cherry, Pear, and Plum trees, two-thirds with the first, and the remaining three in about equal number occupying the other third. The Apple trees are all wrecks, dying back by feet in the young limbs, and all teeming with swellings and excrescences caused by the canker fungus (*Nectria ditissima*). The Pears are perfectly healthy, Hessele and Aston Town fine specimens; Cherries free from gum, Elton and Bigarreau fine trees; Plums moderate, Victoria best. The orchard is in grass, mown, and not manured, but a portion where the Apples have failed is planted with Gooseberries and Currants, and these are very healthy. Of course, the Apples fail for lack of "management;" if so, why not the Pears and Cherries? A trench was being cut near for laying sewage pipes, and it revealed good soil down to 3 feet or more, when the soil proved heavier and redder as the chalk was approached at about 6 feet depth, which, instead of being white, was quite discoloured and red-rusted. The iron had been washed out of the surface soil and accumulated with the alumina over the chalk, and that became reddish to a thickness of 1 to 3 feet. The Apple trees were famished—they wanted iron or manure that contained it along with other essential and nutrient elements, but the Cherries and Pears sent down their roots and drew up the food essential to their healthy growth and the production of fruit abundantly and profitably.

Let us pass to a heavy cold soil in the same county (Hertfordshire). Analysis by Dr. Voelcker:—

*Organic matter and loss on heating	...	...	5.64
Oxide of iron	...	...	4.39
Alumina	...	...	6.36
Carbonate of lime...	...	...	13.53
Sulphate of lime	...	...	0.22
Magnesia	...	...	0.43
Potash	...	...	0.43
Soda...	...	...	0.25
Phosphoric acid	...	...	0.14
Insoluble silicates and sand	...	...	68.57

100.00

*Containing nitrogen	...	...	0.28
Equal to ammonia	...	...	0.34

As compared with the analysis of Mr. Kruse's soil, that just given shows deficiencies chemically of sulphate of lime, 0.04; magnesia, 0.24

potash, 0.08; and phosphoric acid, 0.10; the two last are the most important to apply to the soil, because they are most abstracted by fruit trees and taken off the ground in fruit, but it is much better in the other most important element to be applied to the soil in the production of fruit, namely, nitrogen 0.11, equal to ammonia 0.13 per cent. Mr. Kruse's soil is mechanically 14.30 better than the Herts soil, that is, in insoluble siliceous matter, much poorer in iron (1.01), alumina 1.91, and carbonate of lime 9.62.

The lesson is this—the Herts soil lacks mechanical texture and chemical constituents—potash and phosphoric acid; the Leeds soil, nitrogenous matter. The Herts soil is suited for Plums, so is the Kent (Mr. Kruse); Apples succeed on Paradise stocks on the Herts soil; Pears on Pear stocks produce pale, sickly foliage, grow freely, and hardly ever canker (note the fact—oxide of iron, 4.39); the leaves blister and drop off, and the fruits refuse to swell, and are spotted and cracked. "Artificials have been tried—none any use." Trees on Quince only live about three years, and then gradually die off. A similar soil to the Herts was made suitable for a general fruit garden by burning a foot of the clay beneath the ameliorated top soil, mixing all together so as to form a staple 2 feet 6 inches deep. This materially improved its texture, sun, air, and rain being able to act more beneficially, whilst the store of potash and phosphoric acid had been opened.

Iron, unless forming a pan or disproportioned, has no predisposing or direct influence in causing canker, and in what direction it may be employed as a curative is merely conjectural. Only a few years ago it was considered the active agent in the production of chlorophyll (the green colouring matter of plants). Hoppe-Leyler, however, found that chlorophyll contained phosphoric acid, and Herr C. Loew proved that iron alone was not sufficient to cause the chlorophyll layer to assume a dark green colour when it was pale and yellowish. Mr. Kruse can prove this, and form an idea of the extent to which iron is likely to assist him in subduing canker. I will on another occasion suggest an experiment or two to Mr. Kruse by which he may possibly obtain an object lesson as to the manures best calculated to assist his culture.—G. ABBEY.

(To be continued.)

## DISCUSSION ON POTATOES.

### POTATOES IN SCOTLAND.

IN writing of Potatoes it is a safe preliminary to remark that they are made or marred according to the soil, or, in other words, varieties have to be selected to suit soils. And yet another remark is required—that is, no vegetable is so much at the mercy of the cook, and along with that, it may be added, that tastes vary so much as to what constitutes quality in Potatoes, that one has always a difficulty in deciding on their merits until a trial is made by oneself.

If a Potato is sufficiently floury a very large proportion of consumers are perfectly content to accept that condition as finally settling the question of good quality. The Ashleaf Kidney, The Don, and the Dunbar Regent furnish examples of Potatoes of the highest table quality. The Champion I should place as the lowest in quality; albeit the Champion is floury to a degree. Up to the present the best varieties I have are these—Early Puritan for earliest, and if need be second early, too; Sutton's Early Regent, though I have no doubt that this sort will be displaced before long, as Myatt's has been by Puritan. For autumn I think Sutton's Seedling is as good as any I have tried, and for later use The Bruce. Sutton's Seedling is, of course, known as a second early, but I find it very good for autumn, and after the experience of another year I think more than ever of it as a good table Potato, combined, as that qualification is, with its abundant cropping qualities. Other kinds that can be recommended are Windsor Castle, Matchless, and Jeannie Deans. The first and last named of the above trio have to be tried again, but I certainly think they may prove standard sorts.

Potatoes when well grown are still a paying crop. It is current that two years ago a Lothian farmer, with the profits from his Potato crop, could have bought the land he cultivates; and during the past season an Ayrshire farmer is said to have done equally well with earlies.—B.

### QUALITY IN POTATOES.

BRAVO, Pat Murphy! But you have to thank a Saxon for supplying what you in your hereditary excitement omitted. "The proof of the pudding is in eating," is a very old proverb, but not less true is "The proof of the Potato is in the cooking." Why did not Pat Murphy (page 34) tell us this? Because he (and naturally too) assumed that even the wilful Saxon always boiled his "taters" in their skins. This poor Saxon does, but alas! he finds himself in a sorry minority. He, however, is in full agreement with Pat as to the quality of the old Regent and Lapstone; but does not the well-known quality of the Regent rather upset "W. T., Blantyre's," axiom (on the page alluded to) that quality means yellow flesh?—EAST ANGLIAN SAXON.

### SOME GOOD VARIETIES.

MY few lines seem to have called forth some very interesting contributions, and perhaps you will allow me to give my experience after growing very many varieties for the last fourteen years. Every new variety I invariably obtained twelve years or fourteen years ago, and I was very fond of exhibiting a collection at the neighbouring shows. In the multitude of varieties there is no wisdom, and I cannot recommend

more than eight or nine varieties to be grown, except in cases where exhibiting is carried on. Too many kinds necessitate much trouble in keeping separate, and occupy so much space that they are not desirable. I have ever found that yellow-fleshed varieties are far away the best for flavour (more meaty, if I may be allowed to use such a word), and I firmly believe more nutritious. There is a great deal in what "Pat Murphy" states. I do not believe the present handsome Potatoes are equal in quality to some of the old, and although I have not even seen a Lapstone for twenty years or more, I have a very lively remembrance of what a splendid quality Potato it was; but it deteriorated in cropping so much—seemed sick of the soil—that I gave it up, and have never seen it since. The round Potatoes I used to get in London eating houses twenty or even fifteen years ago were invariably of good quality, but now one does not get such a good Potato at the very same places.

"A. D.'s" contribution, page 34, is very interesting, giving a description of so many varieties, with most of which I am well acquainted. Laxton's Early Short Top is, I am glad to see, appreciated by "A. D.," but he mistakes the other Potato. It is Sharpe's Victor, not Albert Victor, which I do not consider a desirable variety, whereas Victor is good. Mr. Molyneux and "A. D." both speak highly of Sutton's Ringleader, and I shall be tempted to try it before long. So far I know nothing to beat Laxton's Short Top and Victor for earliest crops. To follow these I have Beds Hero and Sutton's Seedling, which for many years I have ever found trustworthy both on very light and very heavy land. I consider these two are quite sufficient for midseason, but if another must be added it cannot be bettered than by Laxton's Victorious, a heavy cropping kidney of flattish shape, and of first-class quality. Laxton's Reward, Sutton's Satisfaction, and The Bruce are amply sufficient for main crop and I believe cannot be excelled. "A. D.," who, like me, appreciates a good yellow-fleshed Potato, cannot do better than try Reward, for it is the best flavoured Potato I have tried of recent years. I have now selected eight kinds, which will be found amply sufficient for all ordinary purposes, and can be very well shortened. If two coloured Potatoes are desired to help an occasional exhibit or for the table, Vicar of Laleham and King of the Russets are as good as any I have tried. These ten varieties have been selected from, I should say, quite 100 that I have thoroughly tried.

In conclusion, I must state that I have grown Victor on both light and heavy land, Early Laxton on heavy, Beds Hero on heavy, Sutton's Seedling both on heavy and light, as also Victorious and Satisfaction. Reward and The Bruce were grown on heavy soil, with Vicar of Laleham and King of the Russets on light land. These few notes may be some guide to others, and I do not think they will be found in any way misleading.—H. S. EASTY.

### TOO MANY VARIETIES.

THE discussion on Potatoes seems likely to prove quite as interesting as that which has been carried on in the *Journal of Horticulture* with regard to Apples. Mr. Molyneux, on page 36, is, I think, not very far wrong when he says half a dozen varieties are sufficient to supply the wants of a good sized family. Unless required for exhibition purposes a large number of varieties is not attendant with satisfaction at the dinner table, by reason of the varying qualities. The cook, too, has good reason for complaint when so many kinds are grown for home use, because in cooking Potatoes differ materially in the treatment necessary to present them in the best possible form. On light soils there is greater uniformity of quality than on heavy clayey land, as Mr. Molyneux points out, and there is less complaint heard concerning bad flavour and non-floury character of the tubers when they are obtained from light soil than from that of an opposite nature.

On the page alluded to "A. D." names twenty-four sorts, calculated to cover a long season, but for all practical purposes—save that of exhibiting—a fourth part, I consider, would cover quite as long a season, and that, too, with more satisfaction to all concerned. With us Snowdrop is the best second early, and Windsor Castle the favourite main crop, Magnum Bonum continuing an excellent succession till the early Ashleafs are ready.

Out of the many sorts grown in this garden during the past year or two, none proved so good a disease-resister as Sutton's Windsor Castle, nor did any other yield so heavy and uniform a crop, and several "trial" and exhibition sorts will be discarded to give place to this variety. Abundance, Satisfaction, Sutton's Seedling, Nonesuch, and Masterpiece were all grown, but none bore any comparison in the quality or weight of crop with Windsor Castle. With one object only in view, namely, that of supplying a good article that must give all-round satisfaction, where is the need for endless sorts of Potatoes, when two or three will do so much better? For exhibition, of course, variety must be had, but in this, I think, societies would do well to reduce their collections in point of numbers of varieties required.—W. STRUGNELL, *Rood Ashton*.

### SUTTON'S SATISFACTION POTATO.

SO much did this remarkably fine flattish round Potato come to the front in the course of last summer and autumn, that I obtained a few tubers of it from several sources, and found in all cases that it was excellent, cooking admirably, and giving white mealy flesh and very good flavour. It is probably the heaviest cropping variety in cultivation, but it is also a common mistake to grow it on rich garden soil. If gardeners would limit their garden crops to the first early or more refined sorts, that would be comparatively small tubers in the fields, and plant

all their late strong growing large tubered kinds in field ground, they would have tubers of more even size, better quality, more free from disease, and on the whole far more useful than rich garden soils give. Satisfaction and other of these large tubered kinds are specially fitted for allotment growth also, because in these the soil is rarely too rich.—A. D.

#### POTATO DISEASE.

I CANNOT accept Dr. J. Böhm's statement (page 49) with respect to the Potato disease as conclusive. I have seen myriads of cases where disease spots have displayed themselves in and immediately beneath the skins of the new tubers where there were no abrasions or injuries by insects of any kind. What is to prevent a *Phytophthora* spore from penetrating into the extremely thin delicate cuticle or skin of newly forming tubers any more than keeping it from penetrating the cuticle or epidermis of the leaf or even stalk? As to where the disease spores hybernate during the resting period I thought Mr. Worthington Smith had long since conclusively shown that they hibernated in the soil.

If Dr. Böhm's theory be correct what becomes of all Dr. Jensen's opinions and theories, which we have so generally accepted because they seemed to be so conclusive and practical? We have never yet, in this country, put his protective earthing experience to a practical test. We never had a better opportunity than was presented last summer owing to the frequent rains, but at last it was shown in numberless instances that the ordinary method of earthing, which is far from being truly protective, did not ward off disease attacks. I should require very strong evidence that the disease spores do not directly affect newly forming tubers. It is evident that there is yet plenty of room for experimenting in relation to the preservation of Potato crops from the disease.—A. D.

#### THE NATIONAL ROSE SOCIETY.

I WAS very pleased to find in Mr. Grahame's interesting letter (page 26) that we are much more in accord than usual; and I hope we may become even more united in our views, though it is generally considered that a certain amount of diversity of opinion with plenty of free criticism is good for any Society, even as the Opposition is a healthy stimulus to Her Majesty's Government.

#### JUDGING.

I do not quite agree with his comments on Mr. Shanks' notes on judging. I think that a small grower *may* be as good a judge as a large grower, or even better, but at the same time I believe that the latter has the greater facilities, and all other things being equal is the more likely of the two to be a good judge. I should have thought this was obvious, that experience was one of the first essentials for a judge, and that the larger amount of blooms a man sees the better would probably be his knowledge of the average standard of a good Rose. If we wanted, say, a judge of boys, we should surely choose a large schoolmaster, other things being equal, in preference to one who had but few pupils. Again, though most little growers cultivate about the same sorts, you occasionally find an uncommon variety even in a small stand, and surely the judge who personally knows the greatest number of varieties must have some advantage. Once more, the small grower who has the most intimate knowledge of the "manners and customs" of the few specimens he has of each variety—perhaps all in one aspect and soil and on the same sort of stock—may chance to find his knowledge too minute and particular, and not general, varied, and broad enough. But still all this does not prove that the large grower is necessarily the best judge—it is the old story of "eyes and no eyes" over again—but I think he certainly has the greater facilities and opportunities of becoming a good judge.

#### DATE OF THE METROPOLITAN SHOW.

On this point I fear we are still as far asunder as we ever have been. For, though it is true that Mr. Pemberton's motion if brought forward again at the next general meeting as a "hardy annual," would, whether won or lost, make no difference to the date for 1894, that seems to me to be the very reason why it *should* be brought forward and discussed, as less likely to injure "good blood" than when it would produce immediate effect. Mr. Grahame having won two closely contested games, suggests that the other side should leave off playing; and it is quite possible (for there is a good deal of human nature in rosarians) that if we had won we might have wished the same, though we might not have been bold enough to propose it.

#### MOSS.

Some time ago a correspondent wrote in trouble about his supply of suitable moss, with an inquiry about the possibility of cultivating it. I could not give him any comfort, but hoped that someone else would, and thus give me a wrinkle as well, but there has been no answer. The

Peterborough grower who used green plush or velvet instead of moss (could it have been thirty miles that he told me was his distance from the nearest place where he could get it?) does not seem to have had many followers, and opinions were divided, I fancy, as to the effect. I did not think it looked bad, though not so good as the real thing; but I have always been chary of expressing an opinion on a friend's or rival's moss since a day some years ago, when I and another amateur showed against each other at an out-of-the-way country show. We were then comparatively novices; but I have now a long way indeed to look up to the height he has since attained. I think he must have been more of a novice then than I was; at all events, I felt called upon to say something when the final moment at length arrived, and he silently placed his twelve beside mine. His moss was lovely, I do not know that I have ever seen better, and it was in all innocence that I said, "What beautiful moss you have got!" His answer was a polite "Thank you," but it was evident that my unfortunate speech was taken as implying that the moss was more worthy of admiration than the Roses, and I was so taken aback as to offer no apology, though I have ever since been wanting to make one.

I confess that when I am judging, the moss in any box must be exceptionally good or exceptionally bad to have even one point's influence in the scale one way or the other. Still, it may have an unconscious effect on the eyes and minds of the judges, and we want to do the best we can for our boxes; so it may be stated that the moss that grows on old roofs, either tiles or thatch, is the most effective if it be laid evenly, and especially if it can be induced to keep its colour. It is odd at the end of two or three weeks' showing how little attention we pay to the moss of which we were so careful at first, and really if it is fairly green and tidy the judge in most cases probably hardly notices it at all. The ordinary moss can only be found, as a rule, of sufficient quantity and quality on a north bank on a clay soil, and much of the roof moss that looks so lovely in a mild winter will be found brown and useless in July. Two or three years ago some old thatch which had moss on it that I had marked as good was pulled down three or four weeks before the first show. I got some of the old thatch just as it was with the moss on it, but though I kept it in the shade, constantly watered, it soon lost its bright colour, and turned so brown and dingy that I had to give it up after all.

The experiences of any exhibitor who has been successful in showing really good moss would, I am sure, be welcomed by others as well as by myself, and if accompanied by some rules for the preservation of the colour of roof moss their value would be increased.—W. R. RAILLEM.

#### PROXY VOTING.

THIS may be all very well in certain cases, but the worst of the practice is that it puts into the hands of executive bodies a power which is invariably employed to the detriment of free and generally healthy criticism. Whilst the country subscriber naturally wishes to be free to vote at general meetings of his special societies he is at a disadvantage, that in the case of any discussion arising he is incapable of voting according to argument, but his judgment has been given irrespective of argument. Those who are beaten at a general meeting once or twice should not be so anxious to invoke the aid of the proxy vote, which is always a two-edged sword; but should peg away, and also work up country subscribers to attend the meetings, and thus carry points by force of numbers as well as try force of argument.—K.

#### THE UNCERTAINTY OF BROCCOLI.

FOR the past year or two this is a question that has been brought under notice in a very prominent manner by the action of the severe winters on the plantations of Broccoli, more particularly in the case of early sorts, or rather those which under favourable circumstances are calculated to "turn in" during January and February. Snow's Broccoli, which is perhaps one of the best for maturing early in the year, when the winter is mild, is rendered valueless in my case by the late frost, which has been severe and protracted. Varieties that can be said to have stood such weather unharmed may be set down as hardy; but the variety above mentioned, I am sorry to say, is one that cannot claim such a distinction, at least not in our case. I have a good breadth of "Snow's" that previous to the last spell of frost gave promise of an excellent yield, but now presents a most pitiable aspect, and I shall not plant this variety on such a large scale in future.

Where convenience exists for lifting and storing the plants in otherwise unoccupied fruit houses or heated pits not too thickly together their progress is carried on easily, and heads that could be produced by such methods would now prove invaluable; but the frost setting in so early and severe gave but little warning or opportunity for storing them uninjured even to many who possess that convenience. A pit, furnished with a flow and return pipe is much better suited for protecting and forwarding Broccoli than houses; the latter, when used as a winter promenade, are rendered very objectionable by the somewhat offensive smell that always arise from such vegetables confined under glass. Unheated pits this winter, without an abundance of protective material, would not be of much service because of the vigorous penetrating powers of the late frost. An ordinary 9-inch brick wall was not nearly enough to resist it penetrating the soil within. To those having protective convenience early Broccoli culture would prove remunerative, but disappointment is sure to be rife among growers who must depend on open air conditions entirely.—W. S.

**THE WEATHER IN LONDON.**—The weather in the metropolis during the past week has been rather mild. Sunday opened wet, and rain fell more or less all day on Monday. Tuesday proved fine, but dull; Wednesday being bright and mild with westerly winds.

— **THE WEATHER IN THE NORTH.**—The week ending the 24th has been one of tolerably good weather for the season. There have been slight frosts on two mornings, and the days, although dull, were mild. High winds, with occasional heavy showers from the west, took place, especially during the night. Snowdrops are beginning to appear. —B. D., *S. Perthshire*.

— **SILVER MEDAL ESSAYS.**—Mr. Harry Corlett, foreman in the gardens of Holbrook Gaskell, Esq., Woolton Wood, is the winner of the medal competed for by members of the Woolton Gardeners' Improvement Society, the subject being the "Principles of Heating" with methods of application. The essay is illustrated by sketches that are very creditable to a young gardener.

— **FRUIT FROM THE CAPE.**—A further consignment of fruit from South Africa arrived at Southampton on Sunday 22nd inst. by the Union Steamship Company's R.M.S. "Athenian." This consisted of 334 packages of Apricots, twenty-seven boxes of Peaches, and two boxes of Pears from Cape Town; and 183 cases of Mangoes and Pines from Durban. The fruit was disposed of by London salesmen on Tuesday and Wednesday last.

— **THE MEXICAN JUMPING SEED, or "Devil's Bean,"** is, says "The International Journal of Microscopy and Natural Science," a euphorbiaceous plant of such poisonous properties, that it is used by the Indians to envenom their arrow points. It not having been scientifically identified to satisfaction, Dr. C. V. Riley has made a special study of it. The saltatory property is not intrinsic with it, but is imparted to it by an insect (*Carpocapra saltitans*), which secures lodgment within the Bean and does the work. Dr. Riley believes that the insect is developed in the capsules of several species of the genus *Sebastiania*.

— **COVERING MUSHROOMS.**—At a recent meeting of the Montreal Horticultural Society Mr. John Perrin, in a paper on the "Culture of Mushrooms in Winter," recommended that light sheets of paper, such as newspaper, should be spread over them as soon as the clumps appear, and that they be syringed lightly two or three times a day. Under this treatment they grow faster, become larger, and weigh more, having perfect form and colour as well as improved flavour. If allowed to become to any extent dry and discoloured by the air, they at once acquire an unpleasant taste similar to that of meat which has been too long exposed to the air.

— **BRUSSELS SPROUTS IN GARDENS.**—I find that Mr. Bowerman of Hackwood has arrived at the same conclusion as I had long since, that the large sprouted forms of Brussels are far better suited for field work than for deep, rich soils in ordinary gardens. He finds that all his stems give the sprouts not only too large but very open, and is resolved to come back to some of the smaller hard-sprouted varieties as being better suited for his purposes. If gardeners would plant their Brussels Sprouts on hard soil that has carried a crop of Winter Spinach, and has not been dug for the reception of the Sprouts, they would have far better results. I see no such stems of Brussels Sprouts in rich garden ground as I have seen in the Middlesex fields.—A. D.

— **BOURNEMOUTH GARDENERS' ASSOCIATION.**—There was a good attendance of members at the meeting held on Wednesday, January 18th, when a lecture was given by C. W. H. Greaves, Esq., on "The Potato and Tomato Disease." The lecturer (who illustrated his remarks by diagrams) gave a short account of its first appearance in this country, also of the experiments which have been recently carried out to prevent the attack of the disease, and received the hearty thanks of the members. This Society has now been in existence four years, and is doing much good in the district. Lectures, by able scientific and practical men, are arranged to be given periodically during the year.—H. T.

— **GARDENING APPOINTMENT.**—We are informed that Mr. W. Thorpe, late head gardener at Shipton Court, Chipping Norton, has been appointed head gardener to A. A. Weston, Esq., Holme Grange, Wokingham.

— **DEATH OF MR. J. SHEPPARD.**—We regret to state that Mr. J. Sheppard, who for many years was head gardener at Wolverston Park, Ipswich, died on January 16th, in his fifty-eighth year. Mr. Sheppard was a good gardener and able manager.

— **FROST IN EDINBURGH.**—In the report on the temperature at the Royal Botanic Garden during last month Mr. R. Lindsay stated that frost was registered on twenty-three mornings, indicating a total of 192°. So much frost has not been registered at the Garden for the month of December since 1879.

— **PUBLIC PARK FOR RAMSGATE.**—Two firms having received instructions to prepare plans for laying out the grounds of Ellington House as a public park, the design of Messrs. J. Cheal & Sons, Crawley, has been accepted by the Council, and the contract for carrying out the work has been entrusted to them. The grounds comprise about 13 acres.

— **BECKENHAM HORTICULTURAL SOCIETY.**—This Society held a social gathering in the Public Hall, Beckenham, recently. Mr. A. J. Baker, one of the Vice-Presidents, occupied the chair, and there was a large attendance. During the evening a handsome silver-mounted tea service was presented to Mr. T. W. Thornton, in appreciation of his valuable services as Honorary Secretary.

— **HARDY CARNATIONS.**—Calling a few days since at Messrs. Hillier's Rose nursery, Winchester, I was very much surprised to find what I can honestly describe as some remarkably fine, clean, well-rooted Carnations in pots standing by the side of a nursery cart road, where they had been all through the winter, and perfectly uninjured by frost. Mr. Hillier said he had nowhere else to put them, and certainly nowhere else could they have done better. W. P. Milner, Mrs. Reynolds Hole, and others in large numbers were in splendid condition. The road in question runs due north and south, is very high, and also exposed. I regard the lofty air-swept position as having been in the favour of the Carnations. There were several hundreds of these plants in pots, and standing without ashes or anything else about them.—D.

— **GARDEN LABELS.**—Apropos of the lead labels brought to the notice of the Scientific Committee of the Royal Horticultural Society recently, it may be interesting to state that such are used in many gardens. At Holly Lodge, Highgate, the residence of Baroness Burdett Coutts, Mr. Willard has a useful contrivance for punching the lead labels. This he invented many years ago. It resembles a box about 18 inches long by a foot in width, and 3 inches deep. On the face or lid all the letters in the alphabet are printed, and at the back of each is a hole in which an iron punch, with the corresponding letter on the end, is inserted. By this arrangement the punches are always kept in their proper positions, and a practised hand can, by the aid of a hammer, dexterously punch the names on the narrow strips of lead that are used as labels. For Roses and fruit trees Mr. Willard finds lead labels by far the most serviceable.—C.

— **LIVERPOOL HORTICULTURAL ASSOCIATION.**—On Saturday evening one of the largest attendances in connection with the winter meetings assembled in the Museum, William Brown Street, Liverpool, to hear a paper on "The Bouvardia," by Mr. J. Glover, gardener to Sir A. B. Walker, Bart., Gateacre Grange. The Chairman for the evening was Colonel Wilson, Hillside, Allerton, and, in addition, there were present W. Fletcher Rogers, Esq., Mr. T. White (Chairman of the Association), Mr. R. W. Ker, Mr. W. Dickson, and many noted horticulturists. Mr. Glover dealt thoroughly with the cultivation of Bouvardias as one, two, and three year old plants, also growing specimens for exhibition. A suitable list of varieties was given. A short discussion followed, Mr. Ranger, and Mr. Ker, mentioning two varieties which Mr. Glover had omitted—viz., Purity and Mrs. Green as being excellent in every way. Mr. White, Mr. Sargent, and Mr. Healey following. A hearty vote of thanks, proposed by Mr. Rogers and seconded by Mr. Ranger, was passed to Mr. Glover. Afterwards the adjudicator's award was made known for the essay on the "Cultivation of the Croton," Mr. F. Atkin being the winner. Mr. Atkin subsequently read his paper, and was afterwards presented by the Chairman with the Society's certificate. A unanimous vote of thanks was passed to Colonel Wilson for presiding.—R. P. R.

— THE NEW RAILWAY RATES. — There appears to be much disaffection amongst the growers and sellers of fruit and vegetables in regard to the new railway rates. A correspondent writes to the effect that recently a consignment of Mushrooms, weighing 74 lbs. gross, sent from Southampton, was delivered at Covent Garden, and a charge of 7s. made by the London and South-Western Railway Company. This is at the rate of £9 10s. per ton—truly a most exorbitant charge.

— TOMATOES AND CANCER. — On many occasions it has been reported in the daily and other papers that Tomatoes cause cancer, though there appears to have been but little truth in the assertion. Relative to the question, Dr. Marsden of the Cancer Hospital, Brompton, now writes that the Committee of the establishment wish to publish that, in their opinion, Tomatoes neither cause nor excite cancer formation, but are a wholesome article of diet, especially when cooked.

— THE GARDENERS' ROYAL BENEVOLENT INSTITUTION. — Our reporter was quite elated when he found one of his paragraphs taken from the *Journal of Horticulture* last week, and embodied with verbal accuracy in the leading article of one of our respected contemporaries. The leader writer was, no doubt, under the impression that what he found useful was a portion of the official report, but it was not. We make not the slightest complaint, but only remark that if by accident we are "caught tripping," we are usually favoured with a notice, and now in all courtesy return the compliment.

— CLERODENDRON THOMSONÆ. — When looking through the houses at The Lawn Gardens, Warwick, on January 12th, I was much struck with the beauty of a large plant of the above in full flower. To see this fine stove climber in the height of beauty at such a date is to me a somewhat novel sight. The plant in question covers the back wall of a stove, and being planted out between the flagstone walk and back wall the roots were apparently able to ramble freely in various directions. The necessary damping of the house preventing the soil becoming dry enough to secure perfect rest, a departure from the orthodox method of culture was resorted to. Some splendid long shoots had been produced, and the points of these were cut away, and the remainder trained thinly, so as to cover the whole surface of the wall, the result being that they flowered abundantly nearly the whole of their length.—D.

— ARE WEED KILLERS DANGEROUS? — As you are at all times ready to lend a helping hand to the working gardener, I shall be glad if you will allow me to ask the above question in the *Journal of Horticulture*. The enclosed cutting from a daily paper (in which it is stated that particles of arsenic deposited on walks are blown about with the dust) was handed to me by my employer, with instructions not to use any more weed killer. I have used several hundred gallons, but never felt the least injurious effect except the points of my fingers feeling a little tender for the first day or so after using it. Perhaps some of your correspondents will give their experience, and say if they have known a case of injury through passing over the paths, and if so, how long after the weed killer was used.—T. W. [Is arsenic the active agent in all weed killers? We think not.]

— BRIGHTON "NEW" HORTICULTURAL AND MUTUAL IMPROVEMENT SOCIETY. — Your Sussex and southern county readers will be interested to learn the happy turn horticultural affairs have taken at Brighton during the past year. At the annual general meeting of members held at the Imperial Hotel on Thursday evening, January 19th, under the presidency of Mr. C. W. Catt, the balance sheet for 1892 was presented and passed. From it we gather that their spring show was a success, giving a balance of £42. The summer exhibition was undoubtedly one of the best seen in Brighton for many years, but owing to a rather disadvantageous compromise having been granted to members of another Society, their balance was turned into a deficit of £28 8s. 4d. The amalgamation of the Chrysanthemum Society was now finally confirmed, and Mr. R. Miller, the Chairman of the latter Society, in a few remarks stated that, after paying all expenses and sending a donation of £10 to the Gardeners' Orphan Fund, they had the pleasure of handing over a balance of £112 15s. 5d. Thus the united Societies start 1893 with a balance of £84. Mr. C. W. Catt was re-elected President for the year; Mr. W. Belchan, jun., Chairman; Mr. R. Miller, Vice-Chairman; Mr. T. Billing, Treasurer; and Mr. Mark Longhurst, Secretary. A Committee of twelve gardeners and three amateurs were then elected by ballot from those sitting on the two Committees. May success attend them.—R. I.

— DEATH OF MR. WILLIAM BROWN. — Many readers will regret to hear that after a short illness Mr. William Brown of St. Mary's Nursery, Richmond, died on the 13th inst. Mr. Brown, who was in his fifty-fifth year, was well known in horticultural circles, especially in and near London, and a few years ago his effective groups of plants at the metropolitan shows secured him many medals. Mr. Brown also gained three gold and three silver medals at the great Quinquennial Exhibition, Ghent, in 1888. As a member of the Richmond Town Council Mr. Brown was held in high esteem, and his funeral, which took place on the 17th inst. at Richmond Cemetery, was largely attended by friends of the deceased.

— RAINFALL IN 1892. — The rainfall registered here for the past twelve months is 25.45 inches, only the merest trifle above that of Jubilee year. As compared with 38.52 inches for 1891 we find a difference of 13 inches. Where tree planting is done, such drought as that experienced last year is very hurtful, and in many instances means death to small trees as well as larger ones. We had less than an inch of rain monthly during February, March, April, and May. Up to the end of July we only registered 8.74 inches, as compared with 12.16 inches for 1891, a difference of 4 inches. When we consider that this shows a deficiency of 400 tons to every acre at such a critical period as the first half of the year, it can easily be seen how serious it is to those engaged in tree planting operations.—E. MOLYNEUX, *Swanmore, Hants.*

— FLOWERS BY TELEGRAM. — A New York florist has started a new and successful branch of business which is indicated by the words over his shop: "Flowers by telegraph to all parts of the world." He has arranged with the leading florists in every city in Europe, so that his customers can have their orders carried out without delay. The price of the cable, or telegram, is charged to the customer. A gentleman who wished a bouquet sent to a lady in Paris before she started to the theatre, called in one afternoon lately and gave the order. There were just two hours and a half to do it in, but the flowers were handed to the lady while she sat at dinner. Another gentleman, says "Pearson's Weekly," wished a floral greeting to reach a lady who had left New York for Liverpool, and when she arrived a man with a basket of flowers awaited her as she stepped ashore from the vessel.

— TYING CARNATIONS. — Almost every grower has his own way of tying Carnations, and while many still cling to cane stakes there are some later and more convenient modes. Mr. Dorner's way is at once neat, simple, and convenient. His plants are put in the rows alternately, so that they run in diagonal lines across the bed. At the ends of the beds and at intervals of about 12 feet along them a light wooden bar, supported at each side by an upright, crosses the bed about 10 inches from the surface. This supports a galvanised wire along each row of plants, the wire being fastened at the ends, while the cross-bars along the bed receive each wire in a little nick which keeps it from slipping. The tying material is cotton string, which is worked across the bed from one side to the other diagonally, making it appear in a series of triangles. The tying is very quickly done by two men, one at either side, passing the string across; it is given a loop over at each wire. The great convenience of this system is that while supporting the plant it is not crowded up together, and the string is not in the way when picking flowers. For very tall growers a second wire may be added above the first.—(*American Florist.*)

— BAROMETRIC PLANTS. — The "Petit Traité de Meteorologie Agricole," by M. Cana, contains a list of prognostics apropos of the aspect which certain plants present according to the state of the atmosphere. The following are a few examples:—If the head of *Nitella sativa* droops, it will be warm; if the head of the same plant stands upright, it will be cool; if the stalks of Clover and other leguminous plants stand upright, there will be rain; if the leaf of the Sorrel turns up, it is a sign of a storm; if the leaf of the Willow Grass slowly bends up, there will be a storm; if the flower of the *Convolvulus* closes, it will rain; if the flower of the Pimpernel closes, it will rain; if the flower of the Hibiscus closes, it will rain; if the flower of the Sorrel opens, it will be fine weather; if the flower of the same plant closes, it will rain; if the flowers of the Carline Thistle close, there will be a storm; if the flower of the Lettuce expands, it will rain; if the flower of the small Bindweed closes, look out for rain; if the flower of the Cinquefoil expands, there will be rain, but if it closes the weather will be fair; if the flowers of the African Marigold close, it will rain; if the scales of the Teasel become close pressed against each other, it will rain.

— **IVY-LEAF PELARGONIUMS.**—For the furnishing of the cones or pyramids which present such striking features on the lawn at Lady Wolverton's Coombe Wood residence, Mr. Woodgate winters many scores of plants in pots of diverse sizes, but chiefly in 32's, and the plants range from 4 feet to 6 feet in height. These are tied up to stakes closely together and kept fairly cool, and are really very crowded. As the spring draws on more room and air is given, and as early as is safe the plants are stood outdoors in shelter, where, being somewhat loosened, they break freely, and by planting time are full of buds, and some bloom. Such plants soon furnish a wire cone, and produce masses of bloom all the summer. Young plants are propagated and grown every year to keep up the supply.—A. D.

— **SPRAYING FRUIT TREES.**—Mr. E. S. Goff, of the Wisconsin Experiment Station, writes in the *Canadian Horticulturist*:—"We believe our experiments in preventing Apple scab have shown the Bordeaux mixture to be one of our best fungicides. We used a diluted form of it with good results last season, and would recommend fruit growers to use it as follows: 10 lbs. sulphate copper (blue vitriol) per 100 gallons of water, and about the same weight fresh lime or a little less. Dissolve in separate vessels and mix only when ready for use, as it is best if stirred constantly until sprayed on the trees or plants. For Apples, spray with the mixture once before bloom after growth starts. Spray once or twice immediately after bloom for the codlin moth, adding the necessary amount of Paris green or London purple. Another spraying or two with insecticide added to the Bordeaux mixture may usually be profitably applied. Our experience of last season demonstrates the value of spraying, and confirms our belief that it has 'come to stay.'"

— **ONIONS.**—One of the chief characteristics of the newer Globe Onions is that they have deeper or more globular bases. The Rousham Park Hero and others of the old White Spanish type had either a flattish or even somewhat hollow base, so that bulbs that seemed to be very large were yet very light relatively. We find in the best forms of deep yet flattish Onions Sutton's A1, Anglo-Spanish, Maincrop, and others, and of egg or globe-shaped Onions Sutton's Globe, Wroxton, and Excelsior are of the finest. How far one may be better than another of those it is not easy to tell, as Onions vary on diverse soils; so far the heaviest Onions have been found in Ailsa Craig, although these do not keep well. Bulbs that are of apparently the same dimensions as Rousham Park Hero often weigh from 6 to 12 ozs. heavier because of the deep bases. Those who grow Onions only under ordinary conditions now find that these newer and finer strains give relatively to other sorts fully 30 to 40 per cent. more size and weight in their crops.—D.

— **PEAT MOSS LITTER AS MANURE.**—Apart from its use in the stable, peat moss litter is equally as serviceable in the garden. Whether this is due to its being so highly charged with ammonia when taken from the stable I am not prepared to say. A relative of mine has, however, proved its value by taking it fresh from the heap, broken up very small, and spreading some about 4 inches deep on slates over hot-water pipes in the stove, placing Allamandas, Clerodendrons, and other plants on the litter. As soon as the peat moss became mellow the roots appeared to be attracted through the holes of the pots into it and run in every direction, and stout firm flowering wood was produced. At the present time he has a large plant of Allamanda Hendersoni thus treated, which is still flowering, and looks likely to continue blooming for some time yet. The peat moss litter he has tried for various purposes, and finds it very valuable. I should much like to hear what other gardeners have to say on the subject, as I believe most people use peat moss as stable litter and nothing more.—J. W. WEAVING.

— **LOW TEMPERATURES.**—Referring to the recent frost in the January issue of the *Meteorological Magazine* Mr. J. G. Symons states that "some of the lowest records ever made in the British Isles have been from stations near the Cheviots and between there and Edinburgh, and that seems to hold good in the recent frost. Mr. Selby of Pawston, in the extreme north of Northumberland, reports the minimum of 3° in the night between January 5th and 6th, and adds that at Shawdon, near Whittingham, about twenty miles south-east of Pawston, on the same night it fell to — 2°; but he says nothing as to the quality of the thermometer at Shawdon or where it was placed. Another low record, and this time from verified instruments, is sent by the Rev. G. T. Ryves from Tean Vicarage in the valley of the Tean, above Uttoxeter, in North Staffordshire; he had 4.4° in Stevenson's screen and — 0.6° on the grass. The record at Braemar Observatory was 9° below zero on the grass, or 41 Fahrenheit degrees of frost. The shade thermometer recorded 4° below zero."

— **PROTECTING FRUIT TREES AGAINST FROST.**—It is stated that in California, France, and other countries orchards are protected against frost by means of smoke during frosty nights, and in Victoria (Australia) several agricultural and horticultural societies have decided to promote unanimous action amongst fruit growers for that purpose. It would require something more than smoke to protect fruit trees from the frost we have experienced in this country lately.

— **SPARKLING RAIN.**—Rain which on touching the ground crackles and emits electric sparks is a very uncommon but not unknown phenomenon. An instance of the kind, so we learn from the "Meteorological Magazine," was recently reported from Cordova, in Spain, by an electrical engineer who witnessed the occurrence. The weather had been warm and undisturbed by wind, and soon after dark the sky became overcast by clouds. At about 8 o'clock there came a flash of lightning, followed by great drops of electrical rain, each one of which, on touching the ground, walls, or trees, gave a faint crack, and emitted a spark of light. The phenomenon continued for several seconds, and apparently ceased as soon as the atmosphere was saturated with moisture.

— **"THE ADVERTISER'S A B C."**—The magnitude of the enterprise of advertising, the great agent in trade expansion, is difficult to appreciate, and for conveying an intelligible idea of it we are unable to conceive anything better calculated to effect the purpose than this grand work of the great advertising agent Mr. T. B. Browne, 161 and 162, Queen Victoria Street, London, and Canal Street, New York. The "A B C" comprises nearly 1000 pages, admirably printed and well and attractively bound. Its character is accurately represented in the "Introduction," as follows:—"The 1893 volume of our Directory marks a distinct expansion, covering the journalistic ground more completely than has ever before been attempted. The information given represents an immense number of details, setting forth not only all serviceable particulars regarding the present condition of the press of the United Kingdom and the colonies, but embracing a mass of foreign newspaper data, collected from every corner of the earth and arranged on a plan of easy reference. The foreign and colonial sections in their existing form comprise every journal of importance within the various countries dealt with. The indices hitherto appearing at the end of the work have been considerably elaborated, and now serve the double purpose of indices and classified lists of journals, magazines, &c., and are placed at the beginning of the book; these include daily morning newspapers, daily evening newspapers, London Weeklies, London suburban newspapers, the provincial press (arranged in counties), magazines and periodicals, class and trade papers, and a general list, embodying the whole in alphabetical order. As usual, a number of statistical and literary articles of interest to newspaper people and advertisers are included in the volume, and will, it is hoped, add to its value." It is a marvellous production.

— **SHROPSHIRE HORTICULTURAL SOCIETY.**—The annual meeting of the above important Society was held in the Music Hall, Shrewsbury, on Thursday last, under the presidency of G. M. Salt, Esq. From the report and statement of accounts submitted we gather that the summer Show of 1892 was a success. The Committee hoped and believed that few would be found disposed to dispute the assertion that each year the Society endeavoured, and not without success, to manifest improvement and progress. The financial account disclosed a larger amount of receipts and expenditure than in any previous year since the establishment of the Society in 1875. As an illustration of the large receipts we quote the following figures:—Subscriptions, £414 19s; cheap tickets, sold previous to the Show by the Hon. Secretaries, £667 4s. 8d.; taken at the gates on the two days of Show, £2068 14s. 2d.; and sundry receipts, £591 7s. 4d., making the splendid total of £3742 5s. 2d., and forming an income which, we believe, is unsurpassed by any other horticultural society in the kingdom. After deducting the expenses of the summer Show the handsome profit of £1089 17s. 3d. resulted. The donations given by the Committee of this Society from its accumulated profits, recently purchased fourteen acres of land (at a cost of £3150) adjacent to the town of Shrewsbury, which it is intended to lay out as a recreation ground, and they have also contributed very liberally to local improvements at different periods in sums amounting to over £3500, besides having £1500 remaining invested. We heartily congratulate the Committee of Management and their excellent Hon. Secretaries (Messrs. Adnitt and Naunton) on the wonderful results thus achieved, which could not possibly have been accomplished without great expenditure of valuable time during the many years of the Society's existence. The spring Show of the Society will be held on March 23rd, and the summer Show on August 23rd and 24th. The money prizes in the schedule amount to nearly £720.

— **NARCISSUS PAPER WHITE.**—How useful this Narcissus is from Christmas time onwards, either in the form of plants for decorative purposes or as cut blooms. The purity of the flowers, and their not too heavily laden perfume, are features which ought to commend them at once. Our bulbs were potted early in October, placed outside, and covered with a good coating of ashes. The first week in December some were placed in one of the forcing pits, and by Christmas we were using the flowers for various decorative purposes. Considering the cheap rate at which the bulbs may be purchased, and the ready way in which they can be forced, it seems somewhat strange that this Narcissus is not more extensively grown in private establishments. The bulbs have flowered extremely well this season.—R. P. R.

— **SUMMARY OF WEATHER IN 1892.**—The year was remarkable for the 8 inches of snow which fell on February 15th, and for severe frost that occurred on February 17th and 19th when 0° (zero) was registered. A severe frost also happened June 14th which caused much injury to all tender plants. Barometer, highest reading, 30·62 on March 30th; lowest, 29·07 on February 17th; average, 29·96. Total rainfall was 21·93 inches, which fell on 182 days; the greatest daily fall was 0·85 inches as snow on February 15th; the total fall is 5·37 inches below the average quantity. Highest shade temperature was 84° on July 3rd, lowest 0° on February 17th and 19th; lowest on grass, 4° on February 17th; mean of daily maximum readings 54·87°, mean of daily minimum 38·74°, mean temperature of the year 46·80°, number of days frost in shade 117, number of ditto on grass 183; mean relative humidity at 9 A.M. (taking saturation as 100) = 83·93. A favourable year in this district for all root crops and small fruit, but a bad one for corn, grass and autumn fruits.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— **WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—The annual meeting of the above society was held in the Mechanics' Institute on Thursday last, Mr. B. Cromwell presiding. The Secretary read the report, was of a satisfactory character, and the statement of accounts showed a creditable balance. A special feature in the report was the account of the Floral Concert, which showed a balance of £12, which had been equally divided between the Gardeners' Royal Benevolent Institution and the Gardeners' Orphan Fund. The library is in a flourishing condition, a good number of books having been added during the year. The interest in the essays has been considerably enhanced by valuable special prizes, which have been awarded as follows:—Silver medal, presented by the *Journal of Horticulture*, subject, "Principles of Heating," to Mr. H. Corlett, The Gardens, Woolton Wood; "The Culture of Mushrooms," prize presented by Messrs. Thomas Davies & Co., Wavertree Nursery, awarded to Mr. Wm. Disley, Allerton Priory Gardens; "Hardy Plants Suitable for a Cottage Flower Garden," prize presented by Rev. G. H. Spooner, Rector of Woolton, awarded to Mr. A. Rowlands, The Gardens, Woolton Wood. A cordial vote of thanks was accorded the Secretary and Treasurer for their valuable services during the past season, and they were unanimously re-elected; a similar vote being also the retiring Librarian, Mr. J. Griffiths. Mr. T. R. Burrows was elected Librarian for the ensuing year. The Committee are, with two exceptions, the same as before, Mr. B. Cromwell vice Mr. Breeze, and Mr. W. Edwards vice Mr. F. Davis. The meeting terminated with the usual vote to the Chairman. The next meeting is announced for February 2nd, when Mr. Wm. Disley, the courteous Secretary, will read his prize essay on "The Culture of Mushrooms," and Mr. R. S. Waterman one on "Soils, and How to Treat Them." Mr. Harvey Gibson, Lecturer on Botany, University College, Liverpool, is engaged to deliver a course of six lectures at Woolton, commencing on the 26th inst.—R. P. R.

## FRUIT CULTIVATION AND IMPORTS.

MAJOR CRAIGIE, in his report for 1891 to the Board of Agriculture, refers to the attention which has lately been called to the extending cultivation of fruit in different forms in Great Britain. "A relative large advance," he says, "is now reported." The small fruit area to which he specially refers "has increased in every county of England and Wales, and in some counties by a remarkable percentage, although nearly a third of the English small fruit area is still to be found in Kent."

As I have not seen the statistics of the area of fruit cultivation in the Journal, perhaps you may think the figures which have been courteously forwarded to me by the Board of Agriculture of sufficient interest for publication. I also add the statistics of foreign and colonial fruit imported into this country for the years 1890-92. These may be of interest to the "distressed

agriculturist," who might in many cases do better with fruit than Wheat. The returns appear to be made up to June in each year.—H. R. WILLIAMS, 6, *Lime Street, London, E.C.*

The area under small fruit cultivation in England and Wales in each of the following years:—

1888...	...	...	...	...	36,700 acres
1890...	...	...	...	...	46,200 "
1891...	...	...	...	...	58,700 "

Compared with 1888 there is an increase in 1891 of no less than 22,000 acres. Of this increase 1760 acres were added to the small fruit area in Kent, the area for that county for the year 1890 being 18,061 acres, and for 1891 19,821 acres. From these figures it will be seen that Kent maintains its pre-eminence in fruit growing. Orchards also show a gradual and not inconsiderable increase in area.

In 1881 the returns show	...	...	185,000 acres
" 1891	"	"	210,000 "

an increase in ten years of 25,000 acres. Market gardens also show a considerable advance in area.

In 1881 there were under cultivation	...	46,604 acres
" 1891	"	81,368 "

an increase in ten years of 34,764 acres.

The following table shows the quantities and value of Raw Fruit imported into this country for the years 1882 and 1892, including Apples, for the years 1890 and 1891:—

	1882	1890	1891	1892	Value of Raw Fruit imported 1892, exclusive of Oranges and Lemons.
	Bushels.	Bushels.	Bushels.	Bushels	
Apples	2,386,805	2,574,957	3,147,373	4,514,700	£1,353,812
Pears	—	—	—	637,211	296,545
Plums	—	—	—	413,315	199,953
Cherries	—	—	—	216,990	134,847
Grapes	—	—	—	764,432	394,987
Unenumerated	2,614,056	—	—	841,022	388,141
	5,000,861			7,387,670	£2,768,285

NOTE.—Pears, Plums, &c., were classified as "unenumerated" previous to 1892. The returns for 1892 show an increase over 1882 of 2,386,809 bushels. Oranges and Lemons imported in each of the undermentioned years:—

	1890	1891	1892
Bushels	5,746,135	5,178,667	6,763,276
Value	£1,756,852	£1,591,052	£2,052,561

SOBRALIA LUCASIANUM.

WHEN well grown the Sobralias are exceedingly handsome Orchids, for although the individual flowers do not as a rule last in a good condition for a long period, fresh blooms are freely produced, and so a succession is kept up. Most of the species have brilliantly coloured blossoms, and amongst the best *S. Lucasianum* (fig. 11) must be given a prominent place. A specimen of this was exhibited by C. T. Lucas, Esq., Warnham Court, Horsham, before the Orchid Committee of the Royal Horticultural Society on June 21st, 1892, when a first-class certificate was awarded for it. This is a splendid form, the flowers being of large size. The lip is broad and somewhat flattened, soft rosy mauve in colour, the throat being light yellow. The sepals and petals are white, faintly suffused with rose, the whole making a charming combination.

CYPRIPEDIUM GERMINYANUM.

DURING the past few years numerous hybrid *Cypripediums* have been produced, and to all appearances we shall yet see many more varieties. At nearly every meeting of the Orchid Committee of the Royal Horticultural Society some hybrids are staged, and not a few of them have been certificated. It would be interesting to know, however, why in at least one instance a duplicate certificate has been adjudged; we refer to *C. Germinyanum* (fig. 10), illustrated on page 67. According to the Journal of the Royal Horticultural Society a first-class certificate was recommended for this hybrid on February 11th, 1890, when plants of it were exhibited by Messrs. J. Veitch & Sons and H. M. Pollet, Esq. Messrs. J. Veitch and Sons again exhibited this form at the Drill Hall on January 19th this year, and an award of merit was adjudged for it.

*C. Germinyanum* is, nevertheless, an attractive hybrid, and deserves its duplicated honour. It is the result of a cross between *C. hirsutissimum* and *C. villosum*. The petals resemble those of its first named, the pollen, parent in shape and colour; the dorsal sepal is shining purple edged with green, and the lip suggests *C. villosum* in shape.

#### LÆLIA VIRENS.

So far as my experience is concerned, this *Lælia* does not appear very frequently in other than comprehensive collections. It is by no means a showy species, the flowers being but about an inch in length, and are borne in racemes. The petals and sepals are pale greenish yellow, while the lip is white. This species was,

lacing every portion. It has four strong growths, and two or three good leads showing, and is this season carrying twelve racemes, which, put collectively, make over 500 individual flowers, and is a very fine sight. Several smaller ones are making quick progress. — R. P. R.

#### DOUBLE PRIMULAS.

TALKING with some neighbouring gardeners, the question was asked if the colour of *Marchioness of Exeter* was right, as we all have grown a variety under that name, and according to a coloured plate that I have by me is a flaked variety, and not pink as described in the *Journal* for the 12th (page 29), or are there two under the one name? I simply ask, as sometimes one gets misled, and the trade may make a mistake, of which

FIG. 11.—SOBRALIA LUCASIANUM.

I believe, originally discovered by Gardner in 1837, but was lost sight of for many years. It reappeared, however, in 1879, it being then in the collection of Sir C. W. Strickland, at Hildenley; but since that date *L. virens* has found its way into several well-known Orchid-growing establishments.—ORCHIDIST.

#### SACCOLABIUM GIGANTEUM.

It is always a pleasing duty to note cases of successful culture in any branch of horticulture. A case in point is the excellent way in which Mr. T. Elsworthy, gardener to A. R. Gladstone, Esq., Court Hey, Broadgreen, cultivates the above *Saccolabium*. From a small piece imported a few years ago from Burmah, and which was placed in a small basket in crocks, charcoal, and sphagnum, he has now probably one of the finest specimens of this Orchid in the country. The plant occupies a teak basket about 18 inches in diameter, and is growing in the above mixture, the roots inter-

I see an instance this season. A gardener sent to a firm for *Primula Peach Blossom*, and when the flowering time came round it was nothing better than the old *alba plena*. The principal variety I grow is under the name of *Mrs. A. F. Barron*, and a grand one I consider it where white flowers are wanted. When well grown it stands a long way ahead of the old double, and I find it much easier to propagate. I have been gathering from my plants every week since (the middle of November, and hope to continue till Easter. I enclose flowers of *Mrs. A. F. Barron*, and some of a sport from the same, also a seedling of last season's raising. The flowers are not so large now as at the first gathering.—J. GILBERT, *Merrow Rectory, near Guildford*.

[The flowers of *Mrs. A. F. Barron* are very good and pure, the sport is deep rosy pink, and the "seedling" salmon pink, with broad segments; it is very good and worthy of a name. The *Marchioness of Exeter* is a mottled or flaked variety, but somewhat erratic in colouration. We have seen some flowers nearly white, and others with little white visible on the same plant.]

## NATIONAL CHRYSANTHEMUM SOCIETY.

WE are requested by the Secretary to announce that the annual general meeting of the above will take place at Anderton's Hotel, Fleet Street, E.C., on Monday, February 20th, at 7 P.M., due notice of which will be sent to the members.

## KINGSTON CHRYSANTHEMUM SOCIETY.

At a recent meeting of the Committee of this Society it was resolved to resuscitate the former premier bloom classes, these having for the past few years dropped out of the schedule, offers of special prizes having been made for the best Japanese and best incurved flowers. Also, it was resolved to purchase and offer a further challenge vase, the present one being limited in competition, to the three winners, Messrs. Beckett, Carpenter, and Mease; that will give the considerable attraction of two challenge vases being competed for next November. In compliance with the urgent request of a number of local gardeners it has also been decided to establish several cut flower classes restricted to the parish of Kingston.

## CHRYSANTHEMUM SHOW BOXES.

I DO not think "Sadoc's" (page 55) proposition with respect to the increase of the size of Chrysanthemum flower stands will meet with general acceptance. If exhibitors are allowed to have boxes for Japanese flowers up to any size they like, though not beyond what is prescribed in the schedule, there will be chaos. It has already been so conclusively shown that there is no need whatever for the increase in size of the stands that it is almost certain in a year or two we shall hear no more about it. We have, during the past Chrysanthemum season, got back in our tastes more towards the flowers of form, substance, depth, and quality, and now care less for the huge, coarse flowers. The revulsion will soon lead to the expulsion of coarse flowers from stands, and the more refined, deep blooms will need no larger stands.—D.

## DECLINE IN INCURVED BLOOMS.

I THINK it will be conceded by those able to judge that the incurved Chrysanthemum is declining in popularity, not only as an exhibition flower, but for decorative purposes also. There are two main reasons for this—first, the increase in variety of form and colour of the Japanese section, and their greater adaptability to decorative uses; secondly, it is thought, and with good reason, that the blooms are not so high in quality as they were two or three years since. The reasons for this are not far to seek. Exhibitors have increased beyond the supply of able cultivators. Many persons are exhibitors now who have not had any practical training in the art of culture. Too many of the cultural details are left to young men who have not had much experience in the matter; hence the decline in the quality of incurved Chrysanthemums.

There are plenty of places where 1000 plants for the production of large show blooms are put into the hands of a youth to cultivate. He may be an excellent attendant, but when the crucial time arrives for him to prepare the blooms for show he is deprived of the opportunity to display his knowledge, or even to learn how to dress a bloom. What are known as professional dressers are called in just a day or so before the show to dress the blooms. These men cannot do justice to the flowers for obvious reasons, and the person who has borne all the labour of the season in cultivating the plants is not allowed to see the operation, which would enable him to become a proficient cultivator. In this way the standard of the blooms falls below what it was when the exhibitor combined the cultivator as well. Professional dressers are, in my opinion, detrimental to the desired standard of incurved Chrysanthemums.

## ENGLISH RAISED VARIETIES.

It is pleasing to note what an impetus has of late been given to the raising of varieties at home. When we can have such sterling varieties as W. Seward, James Shrimpton, Princess May, Beauty of Exmouth, Mr. C. Blick, and many others in one season, it makes one think if we cannot absolutely do without the aid of foreigners in this direction, we are not so dependent upon them as we were. With the introduction of English raised varieties I think there is not likely to be so much confusion as at present exists in some others. Cultivators will not need to burden themselves with so many varieties on trial before they can secure the deserving sorts.

It is an interesting phase of Chrysanthemum culture, too, especially when the hybridising part is carried out on some safe line as to which are the most desirable sorts to select as seed bearers and so on. What is wanted are varieties having good blooms on comparatively dwarf plants. These we are in a fair way now to obtain. With such forms as Avalanche, Mrs. Falconer Jameson, and Mdlle. Marie Hoste as types of habit, and Cullingfordi, Edwin Molyneux, and Sunflower to give the requisite colouring, we may in the near future look for all that is desirable in new varieties.

## HIRSUTE VARIETIES.

The catalogues to hand contain an increased number of varieties representing this section. But why do the raisers of new varieties

consider it necessary to append such long names as "L'Enfant des Deux Mondes?" Why not say White Louis Boehmer? One catalogue contains an English raised seedling, ruby crimson in colour, which should give a filip to this section. Since the advent of Mrs. A. Hardy it cannot be said that any variety added has been a success. This one still remains by far the best, only it is so seldom seen in really first-rate condition.—SADOC.

## CHRYSANTHEMUM LOUIS BOEHMER.

THIS variety proves to be well adapted for striking in July to give dwarf plants for decorative purposes. Mr. Gilbert of Burghley had some very good plants of it at Christmas which had been treated in this manner. These were also remarkable for the almost total absence of the usual hairs, causing the flowers to look like one of the ordinary varieties.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

## LORD CANNING—STAKES.

I ENCLOSE blooms of the white Chrysanthemum Lord Canning, which I consider are good for the time of the year. They are grown on the "let alone" principle, I mean not cultivated specially for large blooms. What is your opinion of the stakes sent herewith? They are an idea of my neighbour, and I believe he is going to send them out as "Brooke's Patent." Either for pot plants or border use I find them good, being strong and tidy. They are made in various sizes.—W. J. GODFREY, *Exmouth.*

[The pure white reflexed Japanese blooms, from 4 inches to 5 inches in diameter, equal in attractiveness any we have seen in January, and excel most. The stakes of galvanised iron are light, neat, and practically imperishable, while the attachment towards the base is calculated to render them more firm in the soil than small galvanised wire supports generally are. Experience, however, is requisite for testing the practical value of the new stakes.]

## CHRYSANTHEMUMS FOR LATE FLOWERING.

I ENCLOSE two blooms of W. G. Drover. What do you think of the variety as a late bloomer? I find it most useful, as it stands well when cut; it is also effective for decoration in the conservatory, not liable to damp. Robert Bottomley is also another most useful variety for late work. R. C. Kingston is distinct and telling so late in the season; Leon Frache, Ralph Brocklebank, and Boule de Neige I find good, and should be grown by all those who have to fill the oft returning basket for room and table decorations. Is the bloom of Ada Spaulding true? —T. WEAVER.

[The blooms of W. G. Drover are 7 inches in diameter, and distinctly effective. Somewhat smaller but equally good is the specimen of R. C. Kingston, deep rosy purple, and the pearly white Robert Bottomley is attractive. We presume you have no difficulty in "filling the basket," or so many could not have been spared. The blooms named Ada Spaulding are not in character, and the plant may or may not be correctly named. They are not typical examples of the variety.]

## INCREASED SIZE OF STANDS.

I FEAR "Sadoc" in last week's issue (page 55) fails to grasp the real pith of the case. The difficulty lies not so much in "defective judgment owing to the blooms not having space to show themselves," because if all stands were of a uniform size, all exhibitors would compete on the same lines, and judging would go on without a hitch. Owing to the blooms being packed so closed together on the board, it is a matter of impossibility for the judges to test their solidity without doing damage. This is one of the reasons of small boards being so decried by exhibitors. What we need is a larger board, and an absolute rule as to size and height regarding it.

As regards "legislating for the few to the detriment of the mass," the question naturally arises, Where is all the interest centred in an exhibition? Is it in the first three stands, or is it in the mass? Why should large flowers be squeezed on a board far too small for them because those behind cannot completely cover the same amount of space? Surely this is not a good "object lesson." "Smart" exhibitors are chary of using a larger board because of the known antipathy of judges generally to green lines of board showing between the flowers. Nor is it a matter for wonder that slight mistakes should occur with their consequent unsatisfactory results to exhibitors when we consider to what a fine point keen competition has brought us, and when we see before us two stands of which the flowers differ but little in quality, though materially in general effect. The closer packed of the two looks grand as a whole, not a green patch visible, and as even as art can make them appear, the fact of being close together tending to hide any slight imperfections and irregularities in size that may exist. This is not the case with that where, owing to the blooms having, we will suppose, another inch of space, each one stands almost free of its neighbour, and, should there be a weak point, it would be instantly apparent to every eye; and in any case the stand would exhibit more irregularities in size, for it is impossible to get a dozen blooms the same width and depth. Now to which stand is the prize to be awarded? To that which is most pleasing to the eye? or will the judges overcome their prejudice and reward the intrepid exhibitor for daring to display the slight faults already alluded to?

I should like to add here that judges, in my opinion, are prejudiced only when the two styles are seen in opposition, for I believe 90 per cent. of growers are in favour of reform. So far as I can see, the only weighty objection to be urged against it is the amount of space at

command. If secretaries could see their way to overcome this difficulty the rest should be easy.

I must join with "Sadoc" in thinking little of conferences after the result of the Chrysanthemum Conference. That such a meeting should have been rendered useless is to be regretted.—H. BROWN, *Beaurepaire*.

#### N.C.S. EXAMINATIONS.

MR. GODFREY (page 54) asks me why the Committee could not investigate the Beauty of Exmouth case without fear of a libel suit the same as the Wells' case was gone into? To this I can only say that I am not the lawyer who was consulted, and can, therefore, only assume the reason from the facts at hand. As Mr. Godfrey and one or two others have taken up their line of argument upon a somewhat similar foundation to that contained in his inquiry, it may be useful to point out that what appears to be an apparently contradictory decision in his case is in reality not such. When a notification first appeared in the *Journal of Horticulture* of an alleged irregularity on the part of a member of the Floral Committee, the General Committee at their following meeting nominated the Society's officials as a sub-Committee to go into the matter and report the result. This was done and the report in due time adopted.

The Wells' case, on the contrary, was brought forward some weeks later by a member of the General Committee at one of its meetings, and thereupon fully discussed. It was not deemed necessary to refer that case to a sub-Committee, and it was dealt with then and there upon the motion of the introducer. What seems to be inconsistent is, therefore, Mr. Godfrey will perhaps agree, easy to understand. Two distinctly different questions were gone into by two different bodies, and the sub-Committee that inquired into Mr. Godfrey's complaint cannot in any way be held accountable for what the General Committee subsequently did in the other.

It is to be feared that many of those interested in the controversy, if not some of his actual sympathisers, will consider Mr. Godfrey displays a regrettable weakness in his argument when he says he would scorn to shelter himself behind the law, &c., and more especially as only a few weeks have elapsed since he announced his intention of leaving no stone unturned to clear himself from what I consider a fancied imputation. When a man's honour, integrity, or veracity is really impugned, he is morally bound to avail himself of any legitimate means to protect it, and the law is certainly in the eyes of the world the most efficacious. But Mr. Godfrey is over-sensitive in thinking our decision stigmatises him as a person who has brought an unfounded charge against another. It does nothing of the kind. Mr. Godfrey's opponent would have just as much right to assert that the same decision in face of his sworn statement branded him with a charge of perjury.

Mr. Godfrey being a principal in the matter, and therefore having it very much at heart, cannot see that the two cases are not identical. There is a vast difference between Mr. Wells' charge and his. Mr. Wells had documentary evidence to rely upon, while Mr. Godfrey's allegation, which may be quite as truthful, is entirely based upon mere oral statements. Moreover, Mr. Wells had the courage openly to name the person he complained of, thereby accepting any legal responsibility that attached. It is impossible not to think that had Mr. Godfrey adopted this course in the first instance, he might, even with a weaker case, have had no cause to complain that the Committee were precluded from proceeding with as full an investigation of the Beauty of Exmouth case as he could have wished.

In conclusion, I cannot help thinking that these facts must, in a great measure, have influenced the legal gentlemen who advised the sub-Committee as to the liability they would incur.—C. HARMAN PAYNE.

[The examination into the truth of the two allegations by two separate Committees has not hitherto been made clear to the Chrysanthemum public.

We pass from that to note that as we were the agents, with Mr. Godfrey's consent, in bringing his letter in the "first instance" to the notice of the N.C.S. officials, we are bound to say it did very clearly contain the name of the person he complained of. The Treasurer was very glad to have a copy of the letter, and it was taken in our office by one of his clerks. Mr. Wells' exposure was the result of his inability to get his case considered by the officials, as is evident by the correspondence in our possession.

We have said nothing against the decision of the Sub-Committee, which we published. It does not affect us in the least, but it does others, and our columns have been open with equal freedom to accusers and accused.

We are a little interested in one element of the dual case—namely, the apparently anxious desire of the officials that we should publish the name of a person whom they have *not* censured in one case, while they refrain from publishing the name of one whom they *have* censured in another. We have not the remotest wish to reveal the identity of the censured individual, but we are a little curious to know on what principle the officials reconcile their request to us with their own act of negation. Perhaps Mr. Harman Payne, with his great logical acumen, can explain the matter.

We are at liberty to add that we think Mr. Fowler's proposition is the best that has been made, and Mr. Godfrey has frankly accepted it. Why should anyone else hesitate to do the same?]

CAN you tell us where Mr. R. Dean is, and why he is so silent? He is

generally ready enough with his pen when he sees a chance to score a point or give a rap to an opponent.—A MEMBER.

[We think Mr. Dean is at Ealing, and we have heard that he gives "raps with his pen" on postcards to persons whose articles do not please him. This has not lessened the supply. We almost wish it had, as we have not been able to publish by any means all the letters which have poured in upon us.]

#### APPLE DISCUSSION.

##### APPLE LADY HENNIKER.

THIS is a magnificent variety for cooking. When baked, the fruit, after being cut into slices does not break into pieces like some sorts, but retains the shape previously held. Although this Apple has rather an acid taste when raw, it is one which can easily be eaten when cooked without the addition of sugar. As a cropper it is a capital sort; in strong land it is somewhat liable to being specked in the skin, which detracts from its appearance. It appears to be more suited for sandy soil, although it bears freely enough in that which is heavy and naturally rather wet.—E. M.

##### THE ORIGINAL BLENHEIM PIPPIN APPLE TREE.

To be correct for history I should like you to put a different rendering of a passage appearing in page 36. Cottages now occupy the site of the old garden where the original Kempster Apple tree grew, in Old Woodstock. The gasometers are situated in New Woodstock. They occupy the garden site where I grafted the scions which I took from the old tree.—R. F.

##### APPLE RAMBOUR FRANC.

THE discussion on Apples in the *Journal* has had the effect of bringing many of the best varieties into prominence, and the above is one of such first-rate excellence that I think it fully deserving of a trial by those not already acquainted with its merits. To me it seems a not very familiar or freely planted sort; but for free bearing and good qualities as a culinary Apple it is certainly a very valuable one. It is one of those Apples that is sure to elicit the query, "What sort is this you have here?" by those to whom the variety is unknown, it being most distinct in general appearance. In the "Fruit Manual" Dr. Hogg gives its season as September and October, but with us this year it is much later than this, our supply promising to last for a few weeks yet to come. Apples, however, appear to be very variable this season in their time of use, some reputedly good keeping ones having to be cleared out before their natural season arrives; others, on the other hand, like the one under notice, continuing some weeks later than they usually do. Although I am no advocate for planting simply for the sake of variety, I certainly would advise those who are extending their fruit plantations this season to add this one to their list if it can be procured. Dr. Hogg says it is a strong and vigorous grower, an abundant bearer, and a good culinary Apple—good all-round qualities such as no one can dispute, and such that are not met with in many popular Apples of the present day.—W. S.

##### APPLE LEMON PIPPIN.

WE hear very little of this variety, yet with us on a strong clayey soil it is one of the most serviceable culinary Apples we have. The trees are on the Crab stock and have low stems, the branches being stiff and erect, only a moderately large size of head being attained. Very rarely do they fail to bear well, and this year the crops were heavier than usual. The majority are near the size of Lemons and not unlike them in form. Where most exposed they are coloured somewhat, but the rest were grass green in colour when gathered, and only now changing to a pale yellow. It bakes or boils admirably, and it is not to be despised for dessert purposes. This season the variety promises to keep well, and we most probably shall have Lemon Pippin till March.—I.

##### WALTHAM ABBEY SEEDLING AND DR. HARVEY.

ON page 500 (December 8th, 1892) "A. D." says that he has not grown Dr. Harvey Apple. "J. A. W." also writes on the same page, saying he cannot persuade the growers in North Suffolk that there is any Apple to beat Dr. Harvey. I do not think "J. A. W." would be able to persuade those of his Norfolk neighbours who possess a tree of Dr. Harvey that there is any Apple except the Norfolk Beaufin to beat it. Dr. Harvey appears to have been largely planted at one time in the eastern counties. I used to know where the best trees of Dr. Harvey Apple were when a boy at school in Norfolk. But to return to Waltham Abbey Seedling; my opinion is that there is no difference between Waltham Abbey Seedling, Dr. Harvey, and Wormsley Pippin. I have grown them all, and their manner of growth, flavour of the fruit, shape, and colour is identical. I am at the present time using fruits for the house, which have been grown on trees named Wormsley Pippin. Wormsley Grange is another name for this Apple, both named after Wormsley Grange, near Hereford, belonging to the family of the late T. A. Knight, Esq.—JOHN CHINNERY.

##### APPLE HISTORY—ORIGIN OF THE BLENHEIM PIPPIN.

THE article on "Apple History," in reference to the origin of the Blenheim Orange Pippin, by Mr. Robt. Fenn (page 36), is very interesting. He seems to point out that his grafts taken from the parent stock "long, long" after 1847 formed the source of all Blenheim trees, as he asks, "Where in living arboriculture can be traced trees other than mine directly handed down by grafts from the old original?" I

answer, near here (Crawley) there are many acres of land that were planted by a Mr. Poupard, a nurseryman then near London. They were planted from surplus stock in, or about 1820, and there are a few very old men who helped to do it as boys, and among the trees are many Blenheim Pippins that were in full bearing "long, long" before Mr. Fenn cut the grafts he speaks of. I remember the orchards being old forty years ago, and have a tree that I grafted about 1855 from a full grown fruiting tree growing at another place close by. Here are the trees and here are the men who planted them.

I rather think this work of Kempster must have been an effort of his to gain "fame;" else how comes it that well grown standard trees from a plentiful stock in a nursery (surplus and unsaleable) could have been planted near here in 1820, as they were? It seems more reasonable to believe that someone brought the first grafts or seeds of the variety from Blenheim in Germany at the time or soon after the famous victory by the Duke of Marlborough there in 1704, and named it Blenheim in commemoration of the event and place from whence it came. This would be reasonable, because locomotion was not so rapid then as later on, and it would take nearly 100 years for things to get about in those days; it takes some time now to establish a new variety—some years—and if the variety was first propagated soon after the famous victory in 1704, then there would be time for Mr. Poupard to get overstocked at about the beginning of this century, as was the case.

There are many vicissitudes that might occur to give Kempster a chance to say he raised the tree. All I can truly say for certainty is that these things I have stated are solid facts. These Blenheim trees were old before Mr. Fenn cut his grafts at Woodstock.—B. WELLS, F.R.H.S.

#### STOCK VARIABILITY.

THE note by "A Yorkshireman," on page 36, in your issue of January 12th, commenting on a previous paragraph therein referred to, is very interesting, and suggests to my mind a matter I have not noticed correspondence on. In all trade lists trees are generally offered worked on the Paradise, Doucin, or Crab stocks. Writers to the horticultural papers give their experience and the nature of their stocks, soils, and sometimes situation and locality, and how best their trees succeed, often with the very opposite results—some finding that a variety will succeed with them on one stock, while another finds it no good, or later and slower in growth and bearing. Now, do not many obtain their trees from different sources and worked on free stocks, while they may be on stocks raised from pips, or in the case of dwarfing stock, as Paradise, raised from seed, which flowers may have been fertilised from neighbouring trees? Would not this account for many variable results when the selected varieties have been grafted or budded on to them? seeing the varying influences in trees and plants of different nature by the influence of stock and scion often causing sporting, bud variation, and from which fixations have been secured. Why, then, should there not be some such even hereditary influences in fruit tree stocks in their nature as to soil, adaptability, and bearing condition? There are several kinds of Paradise stocks, and I have seen imported ones making a miserable existence on a stiffish soil, not even growing fit to be worked upon. Several of our leading firms have made selections of different stocks with broad leaves, and keep them true by layering. Have any authenticated experiments been made of selecting similar varieties of pips from fruit grown on trees worked on the various known stocks, and with what marked results on different soils? Any information on this point would be interesting.—T. W. W.

#### CYCLAMENS AND CINERARIAS AT READING.

IN speaking recently of *Primula* progress in Messrs. Sutton and Sons' Nursery incidental reference was made to the *Cyclamens* and *Cinerarias*. So fine are the strains of both, and so admirably are the plants grown, that they merit more than a passing allusion. *Cyclamens* are grown in thousands, in fact they are almost as great a feature as the *Primulas*, and in general excellence they are certainly not inferior. The varieties of the Giant strain are all beautiful selections, uniting free blooming with flowers of great size. Giant White, for example, is the model of what a *Cyclamen* should be. Its flowers are of large proportions and considerable substance, while they are of the purest white. These qualities are allied with a compact habit and foliage of marked beauty. Another splendid variety is that known as Giant Crimson and White, it has all the qualities of the other, differing only in the crimson base to the large white flowers. Giant Rose, Giant Crimson, and Giant Purple vary in colour alone, they have the same qualities of large size and perfect habit as the others.

Perhaps the most remarkable variety for free-blooming qualities is *Butterfly*. It is pure white, and clothes itself with flowers. In habit, too, it is unexcelled. *Vulcan* is the richest in colour, being a fine purplish red, and it is so telling in hue as to deserve special attention. Quite a new break of colour has been secured in *Salmon Queen*, which is bright salmon pink with mulberry base. It stands out perfectly distinct from all the others, and is beautiful under artificial light. It has short, broad, substantial petals. The plant is very compact in growth and a free bloomer. There can be very little doubt that this variety will become popular. It is a pleasure to note the magnificent condition of all the plants. They are very finely grown, and in the most robust health.

The *Cinerarias* are equally noteworthy both for quality and culture. So far as vigour and substance of leaf are concerned the

plants are like healthy field Cabbages, the foliage being broad stout, and leathery. Many of the plants are 2½ to 3 feet across. This in itself would not be enough, but there is high quality in the flowers too, the individual blooms being large, substantial, well-rounded, and the petals evenly folded. Both the self and the belted flowers are superb. Three varieties are grown under name—Sutton's White, Blue, and Red-edged, all being beautiful selections, but there is a very large range of colour besides, these being blended and sold as Sutton's Superb Mixed. In vigour of growth and size of truss the plants leave nothing to be desired, while the fact that these qualities are united with flowers well up to the florists' standard completes the merit of the strain.—A CALLER.

#### EXPERIMENTS WITH PLANTS IN LARGE AND SMALL POTS.

I HAVE been somewhat interested in noting the behaviour of various plants cultivated in pots of different sizes, more especially *Carnations* and *Chrysanthemums*. I am able to send you a few examples of the latter, and I trust you will not make fun of them, accustomed as you are to gigantic specimens. The plants are cultivated for general decorative purposes and affording flowers for cutting. Nos. 1, 2, and 3 are examples of *Avalanche* from plants grown respectively in 6, 7, and 9-inch pots. No. 1 is one of fourteen, the others are members of a somewhat larger family. The best blooms I had of this variety were cut at Christmas, and these were produced on a plant grown in an 8-inch pot. No. 4 is *Peter the Great* from an 11-inch pot, thirty-six to forty blooms on each plant. No. 5 is *Source d'Or* from a 10-inch pot, two dozen to each plant. No. 6 is *L'Ebouriffée*, 6-inch pot, eight blooms. No. 7, *Guernsey Nugget*, in a 9-inch pot, thirty-six blooms. No. 8, *Mons. Astorg* from a 10-inch pot, two dozen blooms.

The remark I have to make about these is that most varieties are unsuitable for cultivating in small pots, though an 8-inch is quite large enough for *Avalanche*. There is a loss both in size and in the number of flowers borne when the plants are grown in smaller pots. *L'Ebouriffée*, *Etoile de Lyon*, and *Mrs. F. Jameson* are examples of others which succeed better in rather a small pot than in a large one. *Mary Anderson* is very suitable for small pots, a 7-inch pot giving one floriferous plant and the blooms of good size; but in the case of the useful cutting varieties, including those of which examples are sent, I find it pays to grow them in pots 9, 10, and 11 inches in diameter. The growth is, of course, somewhat taller, but a much larger number of equally good flowers are secured in much less space and with no more labour. However, I think pots 11 inches in diameter are quite large enough, and in this size three good young plants can be placed at the time of the last potting. Three young plants grown together in 7-inch pots make floriferous bushes when transferred to 10-inch pots.

With regard to *Carnations*, I have flowered plants in pots of from 5 to 8 inches in diameter. The first named size is too small. A plant does fairly well in a 6-inch pot, and that is all. This year I am cultivating a number in 7-inch pots, as this size seems to suit very well. Three plants in a large pot succeed much better than if each were flowered individually in a pot of a smaller size. The same effects were very noticeable in the case of *Fuchsias*, 5-inch pots giving less desirable results with plants of the same age and variety in 7 and even 6-inch pots. The time the plants continue in flower are affected very markedly in favour of the plants grown in the larger sized pots. In the case of *Begonias* this feature is also particularly noticeable. With *Zonal Pelargoniums* the improvement is most conspicuous in the increased size of truss and pip.

*Crotons*, *Ficus elastica*, and *Dracenas*, as examples of foliage plants, do not grow so rapidly or attain the stature in 5-inch that they do in 6-inch pots. The latter is a very good size, as along with a sufficient development of the plants there is no difficulty in utilising them in furnishing, either in groups or in small vases.—A SCOTCHMAN.

[Fancy a Scotchman fearing we shall "make fun" of his flowers! No, we take them seriously. The examples of *Avalanche* *Chrysanthemum* show the same relative differences in the size of stem, foliage, and bloom as the pots do in which the plants were grown. The other varieties are fresh and bright, the blooms being large enough for decorative purposes. Many persons would be glad to have plenty and to spare of such flowers at this season of the year.]

#### THE CLIMATE OF COLORADO.

THE annual meeting of the Royal Meteorological Society was held on Wednesday evening, the 18th inst., Dr. C. Theodore Williams (President) in the chair. After the report had been read, and the officers and Council for the ensuing year had been elected, the President delivered an address on "The High Altitudes of Colorado and their Climates," which was illustrated by a number of lantern slides.

Dr. Williams first noticed the geography of the plateaux of these regions, culminating step by step in the heights of the Rocky Mountains, and described the lofty peaks, the great parks, the rugged and grand canons, and the rolling prairie, dividing them into four classes of elevations between 5000 and 14,500 feet above sea level. He then dwelt on the meteorology of each of these divisions, giving the rainfall and relative humidity, and accounting for its very small percentage by the moisture being condensed on the mountain ranges of the Sierras lying to the west of the Rockies; also noticing the amount of sunshine and of

cloudless weather, the maxima and minima temperatures, the wind force, and the barometric pressure.

Dr. Williams quoted some striking examples of electrical phenomena witnessed on Pike's Peak (14,147 feet) by the observer of the U.S. Weather Bureau, when during a violent thunderstorm flashes of fire and loud reports, with heavy showers of sleet, surrounded the summit in all directions, and brilliant jets of flame of a rose-white colour jumped from point to point on the electric wire, while the cups of the anemometer, which were revolving rapidly, appeared as one solid ring of fire, from which issued a loud rushing and hissing sound. During another storm the observer was lifted off his feet by the electric fluid, while the wrist-band of his woollen shirt, as soon as it became damp, formed a fiery ring around his arm. The climate of the Parks is, however, Dr. Williams considered, of more practical interest, and in these magnificent basins of park-like country interspersed with Pines, and backed by gigantic mountains, are resorts replete with interest for the artist, the sportsman, the man of science, and the seeker for health. Most of them lie at heights of from 7000 to 9000 feet, and so good is the shelter, that usually snow does not long remain on the ground, while Herefordshire cattle in excellent condition are able to fatten on the good herbage and to lie out all the winter without shed or stable.

Dr. Williams predicted for these parks a great future as high altitude sanatoria for the American Continent, especially as several of them have been brought within easy distance of Denver, the queen city of the plains, by various lines of railway. The resorts on the foot hills and on the prairie plains at elevations of 5000 to 7000 feet include, besides Denver, Colorado Springs, Manitoba, Boulder, Golden, and other health stations, which can be inhabited all the year round, and where most of the comforts and luxuries of American civilisation are attainable in a climate where not more than half a day a week in winter is clouded over, where the rainfall is only about 14 inches annually, most of which falls during summer thunderstorms, where the sun shines brightly for 330 days each year, and where the air is so transparent that objects twenty miles off appear close at hand, and high peaks are calculated to be visible at a distance of 120 miles.

Dr. Williams summed up thus:—The chief features of the climate of Colorado appear to be—1, Diminished barometric pressure, owing to altitude which throughout the greater part of the State does not fall below 5000 feet. 2, Great atmospheric dryness, especially in winter and autumn, as shown by the small rainfall and low percentage of relative humidity. 3, Clearness of atmosphere and absence of fog or cloud. 4, Abundant sunshine all the year round, but especially in winter and autumn. 5, Marked diathermancy of atmosphere, producing an increase in the difference of sun and shade temperatures, varying with the elevation in the proportion of 1° for every rise of 235 feet. 6, Considerable air movement, even in the middle of summer, which promotes evaporation and tempers the solar heat. 7, The presence of a large amount of atmospheric electricity. Thus the climate of this State is dry and sunny, with bracing and energising qualities, permitting outdoor exercise all the year round, the favourable results of which may be seen in the large number of former consumptives whom it has rescued from the life of invalidism and converted into healthy active workers; and its stimulating and exhilarating influence may also be traced in the wonderful enterprise and unceasing labour which the Colorado people have shown in developing the riches, agricultural and mineral, of their country.

## NOTES ON CLAREMONT.

### CAMELLIAS.

ONE of the most interesting of houses devoted to the cultivation of the Camellia is that at Claremont. It stands on a very elevated portion of the pleasure grounds, quite remote from any other buildings, and within it the Camellias are planted out in two large raised beds, these being edged by raised stone margins, thus enabling ample depth of soil to be furnished. The plants now are very dense, so much so, in fact, that they form all round a perfect close cropped face of leafage and bud. They reach fully 10 feet in height, and the various sorts give many thousands of flowers over a long season. This lasts from early in December until the end of April. The house is a long span, and being so elevated forms a very striking feature in the grounds. Of course, it is needful to give the bed in which the Camellias are growing good soakings of water occasionally, and that has to be carted to the house from the neighbouring lake.

### LIBONIA PENROSIENSIS.

Under this appellation there is growing in one of the greenhouses at Claremont, Esher, a large number of dwarf bushy little plants in pots that are exceedingly pretty and most valuable for blooming at this time of the year. The plants and flowers, which are reddish scarlet and about an inch long, bear close resemblance to *Cuphea platycentra*. They were raised from cuttings struck in the spring, and have since been grown in very gentle warmth. It is a delightful little plant for the season.

### OLD WALLS AND TREES.

I observed also that Mr. Burrell had been doing his best to give his Plum trees on an east wall a fresh start by taking them clean from the wall, hard thinning the wood; then very liberally coating the wall with a dark brown wash of lime, softsoap, clay, &c., with which to fill in the myriads of holes made in the mortar, where nailing has been practised for perhaps 100 years. When walls get into this condition they

present a peculiar difficulty to the gardener. If, as in this case, the wash be thick enough to coat the wall it does not fill the holes, all of which serve to afford the insects habitation. If the wall face be properly pointed all over it will adhere only if one-half the material be cement, and that will not admit of nailing. The only course left seems to give the face of the wall a coating of cement compost, then wire it over. Of course, in such case the holdfasts for the wire must be fixed before the coating of cement is given; then when that is set the wiring may be done, and the trees secured to them. That for wall trees there is no plan so satisfactory as is that of nailing there can be no doubt; wiring and tying the shoots is at the best but a makeshift. It seldom happens, however, that trees thrive so well on wires as on the walls direct. —A. D.

## GASTROLOBIUM VILLOSUM.

THIS is a very pretty shrubby plant, and one that should be more generally grown for the embellishment of greenhouses and conservatories. As will be seen by the illustration (fig. 12), the flowers

FIG. 12.—GASTROLOBIUM VILLOSUM.

are on small racemes, which are freely produced during the spring and early summer. The standard, or upper portion of the flower, is large and of a dark orange colour, while the wings and keel are claret coloured. The leaves are dark green, terminating in small hooked spines. The stems and leaf margins are thickly set with hairs, from which character the specific name is derived.

The species under notice, as indeed do all the *Gastrolobiums*, require similar treatment to that generally accorded greenhouse hardwooded plants. A compost of fibry loam, peat, and sand will suit it admirably, and rather firm potting is essential. Efficient drainage must also be provided, and careful watering is of the greatest importance.

## KEEPING GRAPES AT FLOORS.

FIGURE 5, in your issue of January 12th, admirably illustrates for what a trifling sum, and with a little tact, a good Grape room might be made. When Mr. M'Kellar took charge of Floors Gardens about eleven years ago there was no Grape room on the place, and advantage was taken of a disused and somewhat dilapidated room in a bothy by having it fitted up with shelves as your illustration shows; and I can corro-

borate all your correspondent says about being able to keep Grapes in it until June. It used to be the practice of Mr. M'Kellar to send old and new Grapes to the table together during the latter part of May, and I have seen Grapes hanging on it plump and sound as late as the 22nd of June.

The room has a lean-to roof, with a north aspect, and being at the back of a late Peach case on the ground floor enables it to be kept very cool, and forming altogether an excellent place for keeping late Grapes in. I fancy, however, Mr. M'Kellar would smile to himself as he read your correspondent's letter detailing "the plan I adopt" of keeping Grapes, he having had the room fitted up, and for a number of years so successfully kept late Grapes in it.—N. F. BARNES, *Eaton Gardens*.

#### FRUIT FORCING.

**Vines.**—*Earliest Forced in Pots.*—These must be pushed ahead to have the Grapes ripe in March. White Frontignan is fit for use first, because it is richer flavoured than the "Sweetwater" Grapes, and colours quickly. Foster's Seedling and Black Hamburgh, though apparently ripe, require a few days to mature after being coloured, otherwise the Grapes are harsh in flavour. Thin the bunches rather freely to induce fine berries, not, however, going to the extreme of making them loose. Maintain a temperature of 65° at night when the Grapes are swelling, falling 5° on cold mornings, but get the heat up early in the day to 65° or 70° on cold days, and 5° more when mild, increasing the ventilation from 70° with sun heat to 80° or 85°. Close early in the afternoon, and if the temperature rise to 85° or 90° after closing, and the atmosphere is humid, the Grapes will swell rapidly. Damp the surfaces also in the early part of the day and before nightfall when the weather is bright. Afford copious supplies of liquid manure, and sprinkle a little of the following mixture on the surface of the top-dressing of loam or manure:—three parts bone superphosphate, two parts powdered saltpetre, and one part ground gypsum, all dry and well mixed, continuing the application until the Grapes change colour for ripening.

*Earliest House.*—Permanent Vines are ruined by hard forcing, and remunerative returns can only be had from full and perfect crops. The Vines started at the beginning of December will now require attention in tying the shoots and stopping them one or two joints beyond the show of fruit where the space is limited, the axillary or lateral growths below the bunch being removed, except those from the two lowest joints, which, with those above the fruit, should be stopped at the first leaf and to each subsequent one as made. Allow no more bearing shoots to remain than will admit of space for the full exposure of the principal leaves to light and air; also the laterals, for their power of elaborating the food supplies is proportionate to their development and advantages. The laterals also should have a fair shade of light, not allowing them to interfere with the main leaves, yet moderate lateral extension is essential to root activity.

Where the Grapes are in flower the temperature should be maintained at 65°, and 5° more for Muscats by artificial means, and 10° to 15° advance from sun heat. Sweetwater and Muscat varieties should have the points of the bunches drawn to the light, assisting fertilisation by shaking the Vines every day or go over the bunches carefully with a camel's-hair brush, and varieties that do not afford pollen freely should have it taken from other sorts, and this dusted over the stigmas after the bunches have been brushed over, so as to remove the "caps" that frequently adhere to the anthers and stigmas. A constant circulation of rather dry warm air is highly advantageous in securing a good set.

Thinning should commence directly the Grapes are set, so as to get as much size in those remaining as possible, but shy setting varieties must not be thinned until the properly fertilised berries can be distinguished by their taking the lead in swelling, as they may when the size of small peas. Great care is necessary in ventilating at this season, providing air in moderate quantity, commencing early (a little at a time) so as not to reduce the temperature, only to prevent its rising too suddenly and too high. Afford a due supply of water or liquid manure to inside borders, never less in temperature than the mean of the house.

*Houses Started at the New Year.*—The Vines are breaking freely and strongly, and require syringing on fine afternoons and damping exposed surfaces in the morning and afternoon, so as to maintain a genial condition of the atmosphere. Avoid a very close saturated atmosphere, as it only provokes the emission of aerial roots from the rods, and these weaken rather than strengthen the Vines. Increase the temperature to 55° at night and 60° to 65° by day, and to 75° from sun heat, gradually advancing the heat with the growth so as to have 60° at night by the time the Vines are in leaf and 5° to 10° more by day. Ventilate carefully and in accordance with the state of the weather. Let the borders be properly moistened, not, however, making them sodden by needless waterings, for that hinders root action, and its effects are frequently seen in shanked Grapes.

*Houses to Afford Ripe Grapes in July.*—These must now be closed, and the house started not later than the beginning of February

to have the Grapes fit to cut early in July. If the borders are partly inside and partly outside the house the latter need not be covered with any protective material, but when the roots are all outside enough leaves or litter should be employed to prevent the soil freezing, as we have found it do in February to a depth of 6 to 8 inches, and the Vine foliage flag in consequence of the roots not affording proper supplies of sap. Outside stems must also be well bound with dry haybands, for if these get frozen the crop will probably collapse in the embryo state. Syringe the rods two or three times a day, depressing young canes to the horizontal line or lower, and maintain a night temperature of 50°, and 5° more by day artificially, with 65° from sun heat. Water inside borders repeatedly if necessary to bring them into a moist condition, for though fresh rootlets are not pushed until the Vines are in growth moisture is essential to the transformation of the stored matter in the Vines into sustenance.

*Late Houses.*—Gros Colman is the noblest berried and Gros Guillaume the largest bunched black Grapes, and to have them really good in quality the Vines require to be started by the middle of February to early March, as they not only need more time than late varieties generally to ripen, but it is essential that they have the full benefit of the spring and early summer sun to develop their growth, and the last two months of summer to perfect their crops. The wood then gets well ripened, and the fruit being thoroughly finished, these are the noblest black Grapes extant. Complete all pruning, dressing the Vines, and cleansing late houses as soon as possible.

Look over Grapes in the store-room occasionally for decayed berries, replenishing the bottles with clear rain water as required. Avoid fire heat as much as possible, affording air to prevent an accumulation of moisture, and maintain an equable temperature of 45°.

*Raising Vines from Eyes.*—These may now be inserted in pots or pans. Select firm, well-ripened wood, making the cuts clean, and insert the buds, eye upwards, in any light friable compost, say fibrous loam two parts, and one part leaf soil, covering them about half an inch deep with a little silver sand under and about the cutting. Pieces of turf about 3 inches square and deep, hollowed an inch deep in the centre on the reverse side, the eyes inserted, one in each turf, with sandy soil, and plunged in a bottom heat of 80°, soon become rooted, and when they have made two or three leaves each, can be placed singly in 6-inch pots, the breaking of the fibrelets outside the turf causing the emission of numberless fibres. This is a better plan than removing the young canes from pots or pans.

*Cut-back Vines.*—Those raised from eyes last spring, and which are not of a strength for fruiting or planting, should be cut back to an eye or two as near the surface of the soil as possible, dressing the cuts with best French polish, and placing the Vines (not later than early February) in a house with a temperature of 60° to 65° at night, and 70° to 75° by day, and when they have grown 2 or 3 inches shake them out and repot. Turfy loam torn up with the hands rather roughly, with a fifth of horse droppings, and a sixth of old mortar rubbish, mixed, adding a 9-inch potful of charcoal to every 3 bushels of compost, and a similar proportion of wood ashes, with a quart each of soot and Thomas' phosphate powder (basic slag) form a capital compost for pot Vines, further aid being given by top-dressings of the mixture previously advised for fruiting Vines in pots, phosphatic, potassic, and calcic elements—the chief requirements of Vines—being best applied when they are in growth. Pots 6 or 7 inches in diameter are large enough for ordinary cut-backs, unless large, when they may have 9-inch, and from these they can be transferred to the fruiting pots. A slight bottom heat is an advantage for these Vines, but it is not essential, a genial condition of the atmosphere being maintained by sprinkling the house and Vines two or three times a day.

**Cherry House.**—Cherry trees foster aphides of the worst kind, and unless a sharp look out is kept, and they are destroyed directly they appear, the pests get into the trusses of bloom and spoil all chances of a crop. Take, therefore, every care to have the trees perfectly clean before the blossoms appear. Cherry trees also are soon ruined by too much heat in the early stages of their growth, especially when the ventilation is indifferent, as it never must be. Commence ventilating at 50°, allowing an increase of 15° with proportionate ventilation, but only from sun heat, closing the house at 50°, 45° being sufficient by day artificially, and 40° at night. Water will not yet be required at the roots where the roof lights have been removed and the borders properly moistened through to the drainage, but there must not be any deficiency, giving a supply when necessary. Trees in pots require due supplies, avoiding extremes. Do not keep the trees constantly dripping with moisture, but syringe only on fine days and early, and damp the surface of the borders whenever they become dry.

Top-dress the borders with partially decayed lumpy manure about 1 inch thick, and when the roots become active near the surface apply a dressing of superphosphate, with a little nitrate of potash—say, two parts dissolved bones and one part powdered saltpetre, with one part of ground gypsum, mixed, applying 4 ozs. per square yard, every three weeks. Be careful, however, with the saltpetre, as too much nitrogenous matter causes a flush of growth, and, unless the fruit has stoned, it is cast in showers. Nitrate of soda for the same reason must be used very carefully. Trees in pots should be surface-dressed with turves, and be sprinkled occasionally with Thomas' phosphate powder, which not only contains phosphoric acid, but a large percentage of lime in a fairly available form, and this assists Cherries in stoning.

**Strawberries in Pots.**—Adverse weather has only retarded the early plants, which have thrown up the trusses strongly, especially John

Ruskin, La Grosse Sucrée, and Vicomtesse Hericart de Thury, the first being a splendid pollen bearer, therefore useful for fertilising the others, which is best done with a camel-hair's brush lightly drawn over the central part of the flower when coated with pollen. The small flowers should be removed, and the fruit thinned early, so that those left may have the advantage in swelling. This is best effected in a brisk and moderately moist heat—say, 60° to 65° or 70° artificially, with 10° to 15° advance from sun heat; and when the fruit commences to ripen a drier atmosphere will improve the colour and flavour of the fruit. Liquid manure should be given freely, but not overstrong, and it must be kept from the fruit, which is best raised on forked sticks well up to the light. Plants advancing to the flowering stage must not be hurried, 50° to 55° being ample by artificial means, and 60° to 65° with sun heat, and free ventilation. Another batch of plants should be introduced between now and the beginning of February, introducing some of the early varieties along with the second early sorts, so as to secure the succession unbroken. La Grosse Sucrée and Sir Harry are excellent early varieties, the latter having the rich mellow flavour and high colour so much esteemed by many palates. President and Sir Joseph Paxton also please most tastes, and Sir Charles Napier is brisk in flavour and brilliant in colour, with plenty of size; whilst Noble, with Auguste Nicaise, produce enormous fruits and heavy crops.

Every care should be taken to have the plants perfectly free from aphides before they come into flower. Scrutinise them closely in all stages preceding the flowering, and upon the first appearance of the pests fumigate, repeating so as to thoroughly annihilate them. If this is done before the flowers open there will be little trouble, if any, afterwards, and it is better that way, as fumigation dries the skin of the fruit, causing it to become brown, and the Strawberries rarely swell well afterwards, but crack or ripen prematurely, and are worthless.

**Cucumbers.**—Seedlings from the sowing made at the beginning of the month should be earthed up, and when that may not longer be done they may be transferred to larger pots or be planted in their fruiting beds, following generally the instructions before given for Melons, using the soil named hereafter. If the seeds were sown in frames lining the beds must be attended to, with mats over the lights at night. The fruiting bed must now be made, or it may be that the seeds of Cucumbers or Melons are not sown before February, which is, all points considered, much the best plan where reliance must be placed solely on fermenting materials. The materials—two-thirds Oak, Beech, or Spanish Chestnut leaves and one-third stable litter—having been thrown into a heap, moistened if dry, turned in a week and again moistened, and again turned, will be in a fit state for forming the bed. Choose a site for a bed with a southern aspect having shelter from the north, as that of a hedge or wall, and higher than the surrounding ground level. If the site is low place some Pea sticks so as to keep the material from being saturated by the wet, and mark out the bed a few inches larger only than the size of the frame. Beat the manure and leaves well down with a fork as the work proceeds, making the bed about 5 feet high at the back and 4 feet 6 inches in front, which will allow for settling, which it will do about one-third. A few Pea sticks placed across and along the bed at intervals prevent overheating and admit of the heat from the lining being conveyed to the interior of the bed.

It is an excellent plan to use frames with double sides, formed by placing inside a lining of quarter-inch boards, less in depth by 9 inches at the back and 6 inches in front than the depth of the frame, kept an inch from the box by nailing strips of board upright on the inside of the box, so as to form an inch cavity all round the inside, and thus top heat is furnished by means of linings against the sides of the box. The bed should be brought up perpendicular, and the frame put on, which will bring up the heat in about a week. Level the surface, replace the frame, and, if the bed is to be used for raising plants, put in sufficient manure to raise the inside to within 4 inches of the top of the inner frame or cavity, placing sawdust, dry leaf soil or spent tan on the manure for plunging the pots in. To raise the plants half fill 3-inch pots with light, rich, moist soil, place one seed in the centre of each, and cover about half an inch with fine soil. Place a pane of glass on each pot, so as to hasten the germination, and remove it as soon as the seedlings appear. The space left in the pots can be occupied with soil as the plants advance and require top-dressing, which is better than potting them. The plants from a sowing made early in February in the manner described will be fit for planting early in March, and will afford a supply of fruit nearly as early as those from seed sown early in January.

If seed has been grown early in January the plants will be fit to plant early in February, forming the hotbed, as before advised, for the seedlings, only using manure for levelling the surface of the bed, and forming a ridge or hillock of soil in the centre of each light about 10 inches deep, and with a flattened top of that width across, the surface of the bed being covered lightly with soil. For planting, see advice given for Melons. The lights will need mats over them at night, and linings must be given from the bottom of the bed so as to maintain a proper bottom and top heat. A suitable soil for Cucumbers is fibrous loam inclined to be light rather than heavy, good warp or alluvial soil answering, perhaps, best of all, the loam being cut about 3 inches thick and laid up so as to reduce the turf. To this, broken up moderately small, may be added a fourth in equal proportions of old mortar rubbish and charcoal thoroughly incorporated. We prefer fresh turfy loam subjected to a gentle charring over a wood fire, but only heating so hot that it cannot be handled with the hands, and this not

only kills the herbage but destroys the germs of every disease or pest, as well as grubs and everything alive. It is the best preventive of the nematoid worms—the eelworms that produce the Cucumber and Melon disease. Manure is best avoided, as the plants can be fed to any extent by liquid applications.

**Winter Fruiting.**—If the plants show signs of exhaustion, remove the surface soil of the bed, and supply fresh three parts loam and one decayed manure and leaf soil, with a quart of wood ashes and a good handful or two of soot to each bushel of compost. Fresh roots will soon ramify through the fresh compost, and then they will take manure water beneficially. Keep the growths tied to the trellis, cut out exhausted growths, and encourage young shoots in their place.

#### PLANT HOUSES.

**Pelargoniums.**—Young plants that have been kept perfectly cool and have not been pinched since the end of September may be transferred into their flowering pots. A compost of good loam, one-seventh of decayed manure, and sand will suit them. Press the soil firmly into the pots, and water carefully until the plants are rooting freely in the fresh soil. Place them on a shelf close to the glass in a cool structure, where they can enjoy abundance of air. Those for later flowering may have the points of their shoots removed, and the plants repotted if necessary. Remove the points of late-rooted cuttings and place into 4-inch pots; about one-fifth of leaf mould may be employed for these. Old plants that were cut back late and have broken thickly disbud if the shoots are too numerous. Water carefully, but do not allow the soil to become too dry, or else the active roots will be liable to suffer. Watch for aphides, and destroy them as soon as they appear by fumigating with tobacco smoke or some of the various materials manufactured for the purpose.

**Zonal Varieties.**—Maintain a dry atmosphere and a temperature of 60° for double and semi-double kinds in flower. If they need feeding it is better to apply artificial manure to the surface than administer liquid stimulants frequently. Keep plants that have done flowering on the dry side to harden their wood ready for shortening back. Any dwarf bushy plants will flower profusely if introduced into gentle warmth. Plants that have been kept dry for some time cut back and placed in warmth to break, and those that have been kept slowly moving during winter, may be placed into their flowering pots. A temperature of 50° will be ample at first. Those for later flowering may have the points removed. For successional flowering cuttings may be inserted in thumb pots singly, and placed on shelves in a temperature of 60°.

**Freelias.**—Where a good batch has been brought forward in gentle warmth they may now be divided into two, placing the later ones in a structure where the temperature does not fall below 45°. The remainder of the stock may be allowed to grow on under cool conditions.

**Bulbs of Various Kinds.**—Now that there is a favourable break in the weather go over at once the bulbs that are plunged in ashes, and remove to cool quarters all that are ready. Whether placed in frames or cool houses admit light to them with care at first until they turn green, or else their foliage will be injured. Keep them perfectly cool for the present; do not attempt to excite them into growth in their present condition. The soil about their roots must not be allowed to become dry, or the atmosphere in which the plants are placed.

**Clerodendron Balfourianum.**—Start one or more plants under the conditions advised for Allamandas. These plants should not, however, be repotted before they start into growth. They do well in the same pot for several years providing they are top-dressed with rich material, and liberally assisted by stimulants during the season of growth. Plants that need larger pots need only have loose surface soil removed, and the drainage from the base. Before potting see that the old ball is in an intermediate state for moisture, and the new soil should be pressed firmly round it. Do not keep plants raised from cuttings last year that have not yet completed their period of rest in too low a temperature, or they will fail to start into growth. A lower temperature than 55° is not safe.

**Crotons.**—Where brisk moist heat can be maintained good well furnished heads that need re-rooting may be carefully notched and mossed. They will soon form roots ready for taking off, and thus have a long season's growth before them. Young plants that have been kept in small pots may, if slight bottom heat can be given, be potted at once; but where plenty of heat cannot be maintained potting must be delayed for a time. At this season of the year the plants should be potted in the houses in which they are to be grown, and the soil must be thoroughly warmed.

**Dracaenas.**—Young stock should be potted at once if they need more root room. It is a great mistake to allow these plants to become root-bound before they are placed into larger pots. Repot plants that are in a healthy condition and need such attention in the course of the next week or two. It is useless to repot any that show signs of having been checked, they never grow freely again. Any damaged plants may be used for grouping, and the stems afterwards cut up for stock. Roots of these plants may be cut up if the stems have been well ripened and brisk bottom heat can be afforded, if not they are very liable to decay early in the season.

**Plumbago rosea.**—This, and its variety coccinea, may be cut well back as the flowers fade. The plants must be kept in heat to induce them to break into growth, so that cuttings can be obtained for another year. Syringe these plants freely, for they are very liable to be attacked by thrip.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### THE LANARKSHIRE HIVE.

I AM sending a piece of comb, would you kindly say whether it is affected by foul brood or not? My Lanarkshire hives have passed through the winter well so far, and bee-keepers having these hives covered as you direct need not fear the keenest weather. I took a first prize for sections worked on one of my Lanarkshire hives in strong competition, beating all the Association.—G. R.

### EARLY BROOD.

By post on the morning of the 13th a small parcel, containing a piece of brood comb, containing eggs, larvæ, and ripe brood, came with the above note. The brood is healthy, but as some of the cells contain dead adult bees this suggests the hive was either short of honey, or the bees, intent on the care of the young during the extreme cold, have been overcome with the low temperature. This case of breeding on the shortest day, when the mercury was nearly at zero, simply confirms our experience and teachings.

### THE WINTER AND PUNICS.

The sixth day of January had the lowest temperature for the season, being from 3° to 5° above zero here, but the air was dry and the bright sunshine was tempting to the bees. The Punics were the first to make their appearance. There is scarcely a young bee in our hives, and therefore, according to some modern theorists, these bees ought to have been dead long ago; they are not only living, but extra strong, without a spot of voided matter on or about their hive, and very few dead bees to be seen. This is almost wonderful after such a protracted period of keen frost.

### CURES FOR FOUL BROOD.

These have for some time past been advised very much upon the same lines as charms against witchcraft, frightening that away which had no existence. Some of them remind one of the doctor's bill sent to the poor widow whose husband had been under his care, "To professional attendance in curing your husband." Some persons of my acquaintance on asking for a cure for foul brood were told to "burn bees and hives;" and this though a charm is alleged to be found that will keep everything sweet and pure—tarred paper. I am truly sorry for persons troubled with blight amongst their bees, and who cannot find a remedy.

I have tarred my hives both inside and outside for a quarter of a century. One of the worst cases of foul brood I have seen during the past decade was in a straw hive with a wide opening in the crown covered with tar felt, and this by a sheet. Common sense taught me long ago to avoid impervious crowns, as described in one of my first articles to this Journal between 1860 and 1862, at the same time as "Langstroth's" article appeared on the quilt. That was many years before Abbott claimed the honour of introducing it.

In order to keep hives free from foul brood they must be airy but without draught, and all the perspiration of the hive carried off; we must, therefore, study to keep the interior of the hive warm yet fresh, and prevent overcrowding with the consequent overheating. Should the plague appear drastic measures must be taken to stamp it out, not by either burning the bees or hives, but by disinfecting the one and putting the others through the purgatorial process. Trust not to preventives in the shape of nostrums, which have proved failures even in the hands of some of our speculative sages, and remember that the moment the volatile principles and essential oils are evaporated all the healing virtues are dissipated in the ethereal regions; besides, the fumes gas or vapour of the so-called cures, to be strong enough to suppress the germs will kill every bee in the hive or expel them from it. It is foolish to allow a diseased cell to remain in the hive in the hope of the nostrum destroying the disease germs. Is it not peculiar that the advisers of certain cures for foul brood are also advisers of burning hives and bees to accomplish the object in view?

If foul brood is suspected and found in any hive now is the best time to separate the bees from the diseased combs and start them afresh as if forming a new colony. It will be well to begin feeding whenever the bees have had a thorough flight. It is a common practice with some bee-keepers, and so successful that I can strongly recommend it.—A LANARKSHIRE BEE-KEEPER.

### TRADE CATALOGUES RECEIVED.

Carter & Co., High Holborn.—*Selected List of Tested Seeds.*

W. Clibran & Sons, Oldfield Nurseries, Altrincham.—*Vegetable and Flower Seeds.*

W. Baylor Hartland, Cork.—*Year Book of Seeds.*

Dobie & Mason, Dale Street, Manchester.—*Reliable Seeds.*

## TO CORRESPONDENTS

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Labels (H. E. M.).**—We cannot give the precise information you require at present, but will with pleasure endeavour to obtain it with the view to its publication next week.

**Double Primulas (E. Ham).**—The trusses and blooms are very fine examples of the old double white strain—a distinct improvement on the type. Your letter cannot be inserted this week.

**Bambusa Fortunei variegata (L. B. G.).**—We have found this dwarf variegated Bamboo perfectly hardy, and it is so distinct that we cannot conceive of any other variety being mistaken for it.

**Staphylea colchica (T. W.).**—Many persons beside yourself find this shrub useful for forcing, and we are glad to note that "the pendulous sprays of bloom and foliage remain fresh and good for several days after being cut." If you placed sprays in the box sent they must have escaped during transit, for after a careful search they could not be found among the Chrysanthemums.

**Variability of W. W. Coles Chrysanthemum (M. M.).**—This variety appears very prone to variation. We have had many blooms more or less yellow, but the one you send is the clearest we have seen. Whether the colour will be retained in plants raised from cuttings can only be determined by experience, and whether a yellow form would possess any great value is somewhat problematical.

**The Loofah or Vegetable Sponge (J. Foster).**—This is the fruit of *Luffa cylindrica*, a cucurbitaceous plant, native of the East. The plant is climbing, like most of the Cucurbits, and attains a height of 5 to 6 yards, supporting itself by the aid of tendrils. We are not surprised that the Sooly Qua Cucumber deprived of its skin when the seeds are perfectly ripe, carefully washed and dried, makes a very fair specimen of "vegetable Sponge."

**Double Italian Hyacinths (Enquirer).**—The flesh-tinted Double Italian Hyacinth is grown by a few persons, and we have seen a considerable "batch" of it in the establishment of a grower of flowers for market, but the variety is not a general favourite, or bulbs of it would be offered in most trade catalogues. We do not know of dealers who make a speciality of the Double Italian, but the vendor who sent bulbs of it mixed with those of the single flowered variety could no doubt supply both separately if requested to do so.

**Tomatoes and Mushrooms (J. F. S.).**—We are not justified in giving the addresses of correspondents who do not send them for publication, and we know that some contributors purposely omit their addresses to prevent letters being sent to them. One gardener had fifty in one week, very few containing stamped directed envelopes, and he felt therefore that he was subjected to expense he had no right to bear if he answered the letters, and if he did not was open to the charge of discourtesy. We will consider the question of forwarding your letter to our correspondent.

**Collecting Orchids (Albion).**—We have no work on Orchid collecting. We cannot with certainty answer your other question, but you can obtain direct information by writing to the Curator, Royal Gardens, Kew.

**Beet for Size and Quality (E. T. H.).**—The variety you name as too small produces under good culture roots large enough for most persons. Nutting's Dwarf Red, which has many synonyms, is medium in size, rich in colour, tender, and well flavoured. If you want a large Beet of dark colour and fine flavour some of the selections of Whyte's Black would meet your requirements, Veitch's Improved Black being a fine form; but it must not be sown too early (say not before May) or it is liable to become too coarse for winter use, though when sown early it is good for autumn use. Pragnell's Exhibition has handsome medium sized roots and deep crimson flesh. It is excellent in quality and flavour when cooked, and is one of the best Beets for general purposes.

**Vines Unsatisfactory (Woodfoot).**—The roots are simply destroyed by some corroding substance which may result from a close, soapy, rich soil deficient in gritty matter, consequently inert through want of oxidation. The only remedy is to provide and mix such materials with the soil as will correct its sourness, and prevent its settling into a close mass again. The drainage must be efficient, concreting the bottom of the border if necessary, laying drains with a proper fall and outlet, and 1 foot in depth of rubble drainage, the roughest at the bottom and the finest on the top. The soil may have one-fourth of calcareous gravel mixed with it, or one-sixth of old mortar rubbish freed of pieces of wood, with two parts of drift sand, and to every square yard of border, of 2 to 2½ feet depth, add and mix with it 28 lbs. of Thomas' phosphate powder (basic slag). Thus renovated, the border may be as good as if fresh loam were procured if the needful supplies of phosphatic, potassic, and calcic elements are provided by surface dressings.

**Making a Pond (S. D.).**—The excavation should be made 1 foot 6 inches deeper and 3 feet wider and longer than the intended pond, and the sides should incline one-half the height or depth. The bottom and sides must be lined with clay, put in in layers of 6 inches in thickness, rammed well down and puddled, so as to form an impervious mass; a coating of gravel may be placed on the surface of the clay and rammed into it. As to the cost, that depends entirely upon the easy means or otherwise of procuring the clay, the distance it has to be carted, and the rate of transit and labour. Another way of making a pond is to excavate sufficiently to admit of a 9-inch thickness of rubble at the bottom and sides of the intended pond, and provide a drain below that if the subsoil is not naturally drained. The rubble may consist of brickbats or stone, broken up to the size of road metal, roughest at the bottom and finest at the top, yet the fine particles must be sifted out, say with an inch sieve, and this material may be used for concrete mixed with one-third of Portland cement, formed into a "running" mixture, and the rubble run with it. This will leave a rough surface, which may be coated 3 inches thick with cement concrete, formed of sandy unbinding gravel and best Portland cement in equal proportions, forming into a soft running mortar-like mass; this brushed over with a half-worn birch broom, gives a pleasing rough surface. The expense of this depends entirely upon the cost of transit of the materials.

**Dressing Manured Ground with Lime (Anglo-Scot).**—There is no practical objection to dressing the ground with lime. The lime will hasten the decay of the organic matter, and that means ammonia. This may be volatilised and lost, or it may be "fixed" by the alumina and iron of the soil; but it is possible that the lime will act in a beneficial manner by giving activity to the micro-organisms (bacteria) by which the ammonia is transformed into nitrites, and those by similar organisms into nitrates—that is, the nitrogen of the soil becomes food for plants, to wit, nitrate of calcium (lime). We have used lime and soot as a preventive of grub in Onions, Carrots, and other crops for many years, and always beneficially. About half a bushel of quicklime was used per rod (30½ square yards) just before the site was got ready for sowing, spreading on the ground while hot, lightly pointing in, and mixing in the upper 6 inches of soil. This makes quick work of worms and slugs, and the decay of the manure is hastened for the benefit of the crops, so that they are flushed at the start and not late in the season. This is important, for when Onions continue growing instead of forming bulbs they are not satisfactory. The seeds were covered in the drills with wood ashes duly moistened, and when the crops were thinned a peck of soot per rod was strewn on them while they were damp with dew. This rendered the plants obnoxious to the flies, so that their eggs were not deposited on them, and the crops benefited by the soot as a manure. Soot is a carbonaceous substance, therefore supplies other elements besides nitrogen (equal to 3.50 per cent.). Use the lime, say half a bushel per rod, as it will assist in the manufacture of nitrates for the benefit of the crops. Pliny, Virgil, and Columella note (nearly 2000 years ago) the benefit to be derived from lime as a manure for Cabbages, Radishes, and fruit trees in rich soils, and Theophrastus, at an earlier date, was well aware of the advantageous use of wood ashes, the effects being similar to that derived from nitrum or saltpetre, though the nitrum of the ancients was probably natrum (nitrate of soda).

**Names of Fruits.**—Notice.—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not

necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (Biddles & Co.)—The Apple is Gloucestershire Costard, a fine fruit. (W. J.).—We can scarcely understand the two fruits coming from the same tree. The smaller symmetrical highly coloured fruit is, we think, Herefordshire Beefing. (Pershere).—Apparently rather small fruits of Bess Pool. (F. G.).—No. 1 is possibly local, and bears some resemblance to Queen Caroline, though two of the fruits are too conical for that variety. 2, Golden Reinette, fine specimens. We have a box containing several Apples without any letter referring to them, and some of the fruits are decaying.

#### THE PREVENTION OF POTATO DISEASE.

NOT always is success the best guide to follow; failure, if only we ascertain its cause, shows us what to avoid, and if its lessons are rightly applied leads to success. In the report of the Woburn experiments for the prevention of the Potato disease by Dr. Voelcker in the new number of the Journal of the Royal Agricultural Society, we have a remarkable instance of this. The sorts under treatment were—Early kinds: Myatt's Ashleaf, Early Puritan, Early Rose, Beauty of Hebron. Medium kinds: Dalmahoy, White Elephant, Reading Giant. Late kinds: Emperor, Schoolmaster, Victoria. The first dressing with bouillie bordelaise was done on June 30th, the earlier kinds having grown sufficiently by then; the other varieties were

dressed for the first time on July 6th and 7th, and the whole were finished before any sign of disease appeared.

By the middle of August, we are told, the early kinds were quite ready to take up. This was done August 10th to 13th, the Dalmahoy's of the medium varieties being also taken up on August 16th. There were no diseased tubers in either of the five sorts, and so far the trial was entirely successful. But on August 24th it was noticed that the dressing had for the most part been washed off the leaves of the remaining plots, and directions were given that the plants should be again sprayed. An interval of a week before this was done left the haulm exposed just when it most required protection, and on September 1st, when the second spraying was begun, disease became visible. It is, therefore, obvious that only up to the time of lifting the early sorts were the experiments conducted satisfactorily. Surely those who controlled the experiments should never have left the haulm from which the first dressing was washed without an immediate second dressing? The report says it was left undressed for a week, and for that reason we are bound to regard the experiments with the medium and late sorts as unsatisfactory. When the haulm attains its full height a change occurs in the epidermis of its foliage, which may be termed a softening, or the first stage of decay; it then becomes a suitable nidus for the resting spores of the disease fungus to lay hold of or become established in, the mycelium then runs through leaf and stem downwards into the tubers, which are more or less affected by it. The theory of disease prevention by means of bouillie bordelaise is a perfect coating of every part of the haulm with it; if the coating is imperfect at first, or becomes so subsequently while the haulm continues green, then the application of theory to practice is at fault, and the experiment untrustworthy.

It may be usefully noted here that, regarded as a test of the comparative value of the different sorts, it proved that for field culture the best Potato among the earlies was Beauty of Hebron, among the medium crops the Reading Giant, and of the late varieties Emperor. Beauty of Hebron is described as a "good early cropper; clean skin; shallow eye; very saleable." Reading Giant is a "good-looking Potato; very heavy cropper; clean thin skin; saleable." Emperor is a "very good cropper; clean skin; plant has very large tops; quite saleable." In bulk of crop Reading Giant was decidedly superior to all others, its weight of sound tubers per acre being upwards of 15½ tons. It is a Potato of excellent quality, which can be recommended for general culture.

Two kinds of bouillie were used, one consisting per acre of 20 lbs. of sulphate of copper, 20 lbs. of lime unslaked, and 100 gallons of water; the other of precisely the same quantities of copper, lime, and water, with an addition of 20 lbs. of molasses, under a suggestion of M. Girard of the syrup probably helping to retain the copper salt more firmly on the leaves, and thus rendering it less liable to be removed by rain. The idea proved entirely fallacious, no advantage whatever being derived from the addition of molasses, and other experiments tend to show that 20 lbs. each of sulphate of copper and lime to 100 gallons of water is the best mixture.

The report is somewhat contradictory, setting forth in one part of it how the whole of the crop of early kinds and one medium kind were taken up quite free from disease in the second week in August; and yet in another part saying that neither the ordinary bouillie bordelaise nor the bouillie bordelaise sucrée had an entirely preventive effect. We should say that certainly in the early kinds it had undoubtedly a preventive effect, for it was not till after the crop of them was taken up that the mixture was washed off any of the haulm, so that from June 30th till the haulm was decayed it was so well protected by the bouillie that disease germs could do no harm. If this view is correct, as we believe it to be, widely different results of experiments are easily accounted for. If the dressing acts as a shield to ward off disease,

to be really effective it must completely envelop every part of the haulm, there must be no flaw in it. From the first application till the decay of the haulm the shield must be intact, and then the disease may probably be prevented. The right time for the first dressing appears to be a matter for watchful experiment, too; if the dressing lessened the crop as it is said to have done in some instances, it was probably owing to some error of application.

#### WORK ON THE HOME FARM.

Instead of selling surplus corn at a loss it is used profitably for rearing and fattening live stock at the farm. A considerable quantity is required for poultry, of which the number has steadily increased till what with four fixed poultry houses, two at the farm and two others near gamekeepers' houses, and several portable ones on wheels, upwards of a thousand hens are kept. It is by separating them in batches of four or five score that they prove healthy and profitable. During the winter the portable houses are brought near the farm in different convenient enclosures, where they remain till spring, when they are drawn from one meadow to another, or about the park at intervals of a few weeks. By feeding close to each poultry house the fowls always keep to them for laying and roosting, unless they happen to be placed near a hedge, when a hen will occasionally make a nest that is easily found. Of pure breeds kept the most profitable are White and Coloured Dorkings, Game, and Minorcas. Excellent table birds are obtained by crossing Coloured Dorkings with Old English Game; the chickens grow quickly, have deep breasts, and compact yet thick bodies. For winter eggs Orpingtons are now generally preferred, and a cross between the White Leghorn and Langshan is much liked for the large supply of eggs which it affords, but we have a decided preference for White Dorkings, and depend entirely upon them for our supply of winter eggs.

Apart from a given number of bacon pigs, the number of sows kept and porkers reared has been regulated by the number of cows in the dairy herd in order that all skim milk might be used daily. We object strongly to an accumulation of milk and whey which becomes sour and unwholesome, and prefer using it soon after it comes from the dairy. The bulk of it now returned from the dairy at once as separated milk is fresher and can be kept longer than skim milk. Mixed with corn meal thinly for sows and porkers, thickly for pigs fattening for home use or for market, it forms the most nourishing food. Upon the principle of buying in a cheap market and selling in a dear one several more young Suffolk sows were purchased about a year ago; these had their second and third farrows of pigs during the year, and proved an excellent investment. By these and similar means corn is turned to much better account than if it had been sold at a price which precludes profit. We take care not only to feed well with it, but also to market well with the eggs, poultry, pork, butter, cheese, mutton, and beef which it helps to produce.

VINTON'S AGRICULTURAL ALMANAC for 1893 answers well to its title of "A Year Book for Farmers and Landowners," and further as abounding with "facts, statistics, figures, prescriptions, guidance, information—on crops, live stock, soils, implements, manures—for the estate, the farm, the farm house—the landlord, the tenant, and the labourer." To this summary of contents given on the first page of its cover it makes an entirely satisfactory response upon perusal. Tables are its leading feature; it also contains several interesting articles, and portraits of some men of note in the agricultural world.

#### REMARKS.

- 15th.—Bright sunshine all day but cold N.E. wind.  
 16th.—Almost continuous slight snow or sleet from 8 A.M., changing to drizzle about noon and to steady rain later, which ceased about 7 P.M.  
 17th.—Dark and overcast early; slight drizzle, freezing at it fell, about 11 A.M., changing to sleet about noon and to snow at 1 P.M.; depth at 4.30 P.M., when it had practically ceased, three-quarter inch; slight drizzle or sleet in the evening.  
 18th.—Wet from early morning till about 11 A.M.; fair after 1 P.M.; clear night.  
 19th.—Overcast day; fine night.  
 20th.—Overcast early; occasional sunshine after 11 A.M.; bright sunny afternoon.  
 21st.—Cloudy early; fine and sunny from 10.30 A.M. to 1 P.M.; cloudy afternoon.  
 A very ordinary January week; temperature not far from the average, but the soil remains cold.—G. J. SYMONS.

HAVING been elected a member of the Committee of the above Institution at the recent general meeting, I hope I may be excused for approaching my fellow gardeners for the purpose of endeavouring to influence their minds in favour of a more general and generous support of its funds. It cannot be said that I am asking others to do what I have not attempted to do myself, as I have contributed in one way or another between £70 and £80 to this great, good, safe and well-managed Institution.

It is difficult to understand why all gardeners do not rally round this splendid property of £29,000, especially when it is said that every shilling of it is their own. One would think that even from motives of selfishness, if from no higher, every gardener would strive to do all in his power to promote its usefulness and prosperity.

There cannot be less than 30,000 gardeners, nurserymen, and others engaged in horticultural pursuits who are, or ought to be, interested in its welfare, and if as many of these as can afford it subscribed their guinea a year, and if the remainder who are unable to do this were to collect small sums amongst themselves annually for the benefit of its funds, the question of old age pensions, as far as it relates to gardeners, would be solved.

Objections have been advanced by many persons against the Institution because it is not founded on the lines and principles of a benefit society, where a member can claim help at any time in case of need. On the surface this may appear to be a reasonable objection, and I am afraid has been the cause of many not subscribing to its funds; but I think on a little consideration that this objection may be proved to be an erroneous one, especially as in the case of gardeners whose wages are scarcely now stopped in time of sickness, and who, therefore, do not feel the pinch of poverty at this time like mechanics and others who are paid by the hour, and whose pay is stopped when work ceases. As bearing on this point, I may say I have been a member of a benefit society for upwards of twenty years, paying about 22s. a year, and if I am to remain a benefit member I shall have to go on paying that sum as long as I live, and in case of sickness and permanent disability from work I am entitled to 10s. a week for the first year, about 7s. the second year, and after that I believe the pay is reduced to 3s. per week for life. Let me ask my fellow gardeners who are still sceptical on this point to compare this with the advantages offered by the Gardeners' Royal Benevolent Institution, even from a benefit point of view, where after subscribing a guinea for fifteen years, or £10 10s. down, a member is almost certain to be placed on the pension list if he is of good character and incapacitated from work and in want, receiving without any further cost or trouble to himself £20 a year for life, whether his life be short or long.

Another objection has occasionally been levelled at the Institution, viz., that some gardeners who had subscribed but little and others who had not subscribed at all were occasionally elected pensioners. On this point I may say that we must not lose sight of the fact that by far the largest proportion of the property of the Institution has been subscribed by people out of pure benevolence for the relief of aged and destitute gardeners, and I for my

part would be very sorry to see this principle of benevolence infringed upon or curtailed in any way; and I hope and believe it will not be allowed to impose a barrier to prevent subscriptions flowing in. The Committee, as is well known, have introduced a clause into their rules, giving almost absolute certainty of election to those who may have subscribed for fifteen years, and the new rule passed at the recent general meeting will give subscribers substantial advantages over non-subscribers, inasmuch that a subscriber for four years will have fifty votes credited to him, and fifty more added for every year subscribed afterwards up to fourteen years.

My appeal in favour of the Institution, even from a benefit and an investment point of view, will, I hope, commend itself to the judgment of your readers. But I beg very respectfully to appeal to my brother gardeners from a higher level than a benefit one. That man's life is a poor and a barren life who lives entirely to himself, and nothing noble or good has ever yet been accomplished without a sacrifice of some sort.

The gardeners of the past half a century (and others interested in gardening and gardeners) have built up a noble standard of garden charity, which is now shedding gleams of joy and brightness round the declining life of many of our fellow workers who have fallen helpless by the way. Let me, then, appeal to all gardeners and others associated with them in the calling to rally round this splendid Institution, and to strengthen it with their active support, that all the deserving in our craft may claim a shelter under its wings in the time of adversity and want.—OWEN THOMAS, *The Royal Gardens, Windsor*.

[We give the prominence to which we feel the strong appeal of Mr. Owen Thomas is worthy, on behalf of one of the soundest and most useful charities in the world. We do this in the hope that the Institution, strong as it is, will be still further strengthened, and be able to meet the claims upon its resources of many a once able gardener who can no longer labour and who finds it hard to live through his few remaining years. True, it is that the Institution sheds "gleams of joy" in the homes of those who are recipients of its benefits; but correspondingly keen must be the disappointment and anguish of those candidates, equally worthy and needy, who fail each year to become participants in its funds.

Having regard to the uncertainty of the lives of pensioners—and we all wish they may be long and happy—no other method of dispensing its funds than the present one could be resorted to without impairing its stability. We fear—indeed, have heard it said—that the Institution is rich, and that no gardeners who have supported it should suffer want. We rejoice in its strength and in the great good it has done and is doing; but it is not rich enough to do what its officials so ardently wish with the amount realised by its funded property.

The Institution is prudently and economically managed. We are proud of it, and should like for gardeners to feel it an honour to be enrolled on its list of subscribers. The new rule alluded to by our correspondent we hope will induce many who are able to spare a guinea a year to invest it in this charity, which is as safe, so to say, as the Bank of England. Sorry we are to know of many who work in gardens intelligently and well who find their family claims so pressing that they do not find themselves able to do what they would like in supporting institutions that might eventually be in the highest degree beneficial to themselves and their families. But while recognising the existence of difficulties of that nature it must still be a fact that a still greater number of gardeners could, by making some slight sacrifice, set aside about 5d. a week, or less than 1d. a day, and so qualify themselves to become recipients of £20 a year, in case of need, to the end of their days, with a then possible grant of a large portion of that amount to their widows.

If fortune should so favour that aid is not needed by the contributors, then will they have great cause for thankfulness, and in no more appropriate way could they show their appreciation

of their immunity from want than in helping to relieve the dire distress into which their brothers and sisters in the craft have fallen. Mr. Owen Thomas is, we may suppose, one of the least likely to become a beneficiary of the Institution, and his thought is not for himself but for others, and we have no hesitation in expressing our strong approval of his appeal, prompted as it is by good feeling and supported by prudential considerations, which we hope may have weight with many thoughtful members of the gardening community.]

### SEASONABLE NOTES ON TOMATOES.

THE beginning of February is an excellent time to make a good sowing of Tomato seed, the plants resulting from which being useful for a variety of purposes. Some of them will be of great service for planting in vacant spaces in fruit houses; others will, if repotted when necessary, develop into large strong specimens for planting in the open air during the last week in May. In cases where a house can be devoted to them, the plants raised from the February sowing generally proves the most productive because they are grown under the influence of a stronger light in the early stages than plants produced from the autumn sowing, consequently they begin to fruit nearer the soil. The plants have, moreover, a sufficiently long season before them to enable the cultivator to take full advantage of the most productive stages of their growth before the dark days of autumn come.

The plan of sowing in boxes or pans answers very well if the seed is sown thinly, but there seems to be a great diversity of opinion as to what is meant by sowing thinly. For instance, some may think that placing each seed half an inch from any other is following that dictum; but I am fully convinced that if we are to obtain sturdy plants the seeds ought to be placed  $1\frac{1}{2}$  inch apart. The seedlings will then have room to develop without crowding till they have become sufficiently well rooted to be placed in 3-inch pots. I have no doubt that many beside myself have noticed that a Tomato plant in its early stages makes a large amount of top growth in comparison to its root extension; so that, unless the seedlings are thinly disposed, the growth becomes crowded before the roots have grasped the soil sufficiently to render transplanting desirable.

A temperature ranging from  $55^{\circ}$  to  $60^{\circ}$  at night, with a rise of  $5^{\circ}$  during the daytime, is a suitable for producing sturdy plants, provided they can be kept near the glass and have a free circulation of air on all favourable occasions. In order to guard against sappy growth, a condition favourable to disease, the plants should receive but little syringing after they are once established in pots; what moisture is required to prevent the attack of insects may easily be provided by damping the floors and stages of the house. A compost consisting of eight parts loam, one part manure from a spent Mushroom bed, and one of burnt refuse, is quite rich enough, and when ordinary garden soil is employed the only addition required is the same proportion of the latter ingredient and a little soot. If the plants are transferred from the seed box into 3-inch pots they will only require one other shift before being placed in their permanent quarters, except in the case of those needed for open air culture, where they have high walls, fences, or buildings to cover. It is in this instance desirable to place the plants into 9 or 10-inch pots to secure large specimens with a few fruits set upon them before they are placed in their summer quarters. Fine crops of Tomatoes are often secured in the open air by following this course. Firm potting should be practised, as it not only tends to keep the plants free from disease, but also renders them wonderfully productive in a limited space by inducing short-jointed growth, abundance of flowers, and, if other conditions are favourable, a good set of fruit.

When odd plants are wanted to fill vacancies in fruit houses, I keep the plants in pots and partially plunge them in the soil rather than plant in the borders, which are generally too rich for Tomatoes; moreover, I never allow much root run, the attendant evils being strong growth, and a difficulty in securing a good set. In houses solely devoted to Tomatoes the practice of growing the plants in narrow borders or boxes, is, I consider, the best to adopt. If the former are from 15 to 18 inches wide, and a few inches less in depth, and provided with 3 or 4 inches of drainage, a sufficient quantity of soil may be given to enable the plants to support heavy crops, while the roots will be thoroughly under control. Boxes about the same width, and a foot in depth, with 2 inches of drainage, are of the right proportions to secure satisfactory results; but it frequently happens that boxes have to be made much narrower to fit into limited spaces. In such cases the labour of watering is considerably increased.

If well rooted plants which have not been drawn during any

stage of their growth in 6 or 7-inch pots, are planted in positions similar to those above described, they will commence fruiting at a short distance from the ground, and continue to bear till their allotted space has been covered, or till late in the autumn. Specimens answering to the above description should be treated on the single stem system, and if all side shoots are removed, flowers will be produced at every joint. I have tried plants at various distances apart, but have come to the conclusion that when well grown 15 inches from plant to plant is the distance at which the greatest weight of superior fruit can be obtained from a given area. When plants have to be employed which have been unavoidably drawn in the early stages of growth, it is an advantage to lay in a few side shoots near the base to secure fruit to within a few inches of the soil.

The common practice of cutting away a large proportion of the main leaves in the early stages of growth is not one to be recommended, tending, as it does, to prevent the fruits swelling freely, and also encouraging the production of numerous side shoots, which are not required. It is perhaps not practicable to do away with shortening the main leaves altogether, but this necessary evil may, and should be, much more limited than it is; instead of allowing large leaves to develop till overcrowding takes place, it is a much better plan to remove a portion of such leaves when they are young, and thus prevent crowding and the severe check attendant upon wholesale mutilation when the fruits are swelling. When once the majority of them are well advanced in the colouring stage the removal of superfluous foliage is not of so much consequence.

Liquid manure should not be applied till a fair amount of fruit is set, then it may be given regularly at every alternate watering; frequent dressings of the many good manures advertised, or fresh horse droppings, are of great assistance in enabling plants to perfect prodigious crops, and such practices are preferable to planting in rich soil. A method adopted by some market growers is to utilise their Tomato houses for Mushroom growing during the winter, and partially plunge the pots in which Tomatoes are growing, in the Mushroom beds. This is undoubtedly a bad practice, and one which predisposes the plants to the attacks of the dread disease. One large grower of my acquaintance last year suffered severely from this cause, the disease to all appearance being brought about by allowing the roots to penetrate the rich manure.

If the plants are grown throughout in the manner I have described there need be no fear of disease. When, however, the slightest sign of its presence is detected the hot-water pipes should be kept constantly warm, and liberal ventilation afforded, at the same time keeping the plants somewhat dry at the roots. If this treatment is continued for a week all trace of the disease will disappear.

Almost every grower seems to have his own particular selection of Tomatoes, but I think it would be hard to beat Conqueror and Earliest of All for the early crop, Ham Green for the main crop, and a good type of Perfection for exhibition purposes.—CULTIVATOR.

### GROWING MUSHROOMS IN SOIL.

I AM sorry not to have been able to answer the inquiries made by Mr. Cranswick on page 4 of the Journal of the 5th of January sooner. I do not think I can add much to the original article where our practice was described, as it was tried but one year. When the Mushrooms came up in such numbers we were most surprised ourselves, and we shall certainly try the experiment again. Mr. Cranswick asks if the insertion of the ordinary brick spawn would produce equally good results. This we have not tried, but cannot see why it should not, as field Mushrooms grow in loam alone. For this practice the loam should be from old pasture placed on the top of existing borders made very firm and kept rather dry. If the spawn could be made to run and get established I daresay good Mushrooms could be gathered for years without any more future spawnings, but abundance of feeding, either liquid or with Thomson's manure should be given.

One of our houses was built one half on old pasture, the other half on land which had been broken up, cropped, and manured in the usual way for years. Some very large stools of Mushrooms made their appearance from the part of the border composed of the old pasture; on the other half we have never seen any, though all the house had the same treatment, being all planted with Tomatoes and top-dressed alike both with Thomson's fertiliser and ordinary farmyard manure, but no spawn was inserted at any time. I may mention that our soil here is on the old red sandstone formation, and is of fine quality. Everything seems to thrive in it, and we neither use either sand, leaf mould, nor farmyard manure. The Vines in particular thrive well.

As suggested by your correspondent, the length of time the spawn took to run was partly accounted for by the depth it was buried; and late in spring before the border was done up we had no fire heat, the house being naturally a cold one. We expect to gather Mushrooms next autumn from the same border. Even now, though the house is empty and has had no more heat than to keep out frost in severe weather, we see one or two fine Mushrooms are appearing.

We are only beginners in Mushroom growing, and groping our way; also like your correspondent, hunting after information and taking advice, and experimenting as often as we can. By another year we may strike on something new; at all events, we shall be able to speak with more confidence and experience in this new way of growing what is undoubtedly the most profitable crop one can produce. I shall be glad to give to all interested any hints I can through the *Journal of Horticulture*.—W. BUCHANAN, *Forth Vineyard, Kippen*.

### EXPERIENCE IN HEATING.

HEATING glass structures by means of hot water being a matter so closely connected with the cultivation of flowers and fruits, it is of great importance in growing them successfully to know something of the principles by which hot water is conveyed. I will try and make the subject as clear and simple as possible, that it may be readily understood by those whom it would be most likely to benefit. Mr. Fawkes, in his treatise on "Hot-water Heating," thus describes the principle involved:—"The construction and working of a low pressure hot-water heating apparatus is based upon the fact that water is at its greatest density and minimum volume at 39.2° Fahr. Upon the temperature being raised above this point the volume increases and the density decreases. In other words, a cubic inch of water at 40° weighs more than a cubic inch at 60°. It is obvious, therefore, that if we take a given quantity of hot and cold water and allow the two to intermingle, the immediate result of the difference in the respective specific gravities will be that the latter will push the former upwards, so that the hot water will lie at the top, the cold water at the bottom."

Thus we see that water upon being heated becomes lighter, expands, and rises upwards, and the colder water being of greater density lies at the bottom. This is sufficient for all practical purposes. It is rarely that a gardener is called upon to erect a hot-water apparatus; this more intimately concerns hot-water engineers. Those who wish to enter into fuller details can do so by consulting any of the works dealing with the matter. So long as we know the principles upon which the circulation of hot water depends, it is sufficient to enable us to regulate the apparatus by which our structures are heated. The first thing to consider is the number of structures to be heated and the kind of boiler that is likely to suit the purpose best. Boilers are numerous, and some are better adapted for certain places than others. The boiler that is the simplest in construction, and which exposes the largest amount of surface immediately over the fire is the best, and in my experience I have never found any to surpass a good terminal-end saddle-boiler.

### CISTERNS AND PIPES.

Having selected the boiler, we must decide upon the position in which it is to be fixed, and in this matter the stokehole should be constructed sufficiently deep to allow of a proper rise in the pipes to be affixed. Due regard must also be had as to whether there is likely to be any danger from rising water or its ingress in any way, for this would be liable to extinguish the fires, perhaps when the heat was most wanted. A space must also be allowed for holding the fuel near at hand, and this is best arched over with brickwork, the ground levelled, and an opening left at the top, to where it may be carted and easily thrown in. The cisterns for supplying the boiler should be fixed several feet above it in the stokehole, and ought to be fitted with a ball-tap, the feeding pipe brought from the bottom of it and connected with the lower side of the boilers. For large boilers a 2-inch iron pipe would be required. If a pipe of smaller diameter is used it should be of lead, and brass fittings employed on approaching the boiler connection, for fear of corrosion, which might be mischievous. An expansion pipe should be carried up from the top of the boiler into the cistern, to guard against any mishap. Where cisterns have to be filled by hand, great care must be taken that they never become empty. The chimney should be built so as to create a good draught, upon which much of the efficiency of the apparatus will depend. Now, having seen that hot water rises to the highest point, we affix the flow pipe to the top of the boiler, add other connections, always with a gradual rise, until the highest point is reached that we wish to proceed to, and then, with a corresponding fall, the return pipes are brought back and connected with the bottom sides of the boiler, where the colder water is in turn heated and sent along its way.

Main pipes underground should be covered with some non-conducting material, and be in trenches of brickwork, supported at the connections by piers, and upon these, under the pipes, short iron rollers, strong enough to carry the weight, to allow of contraction and expansion should be laid; this prevents the straining of the joints which makes them liable to leak. Main pipes are usually 4 inches in diameter. These mains must be laid in the most convenient manner for connection

to be affixed to them for the various houses which are required to be heated from them.

### LARGE AND SMALL BOILERS.

In some establishments one powerful boiler heats the whole of the structures, another being erected by its side in case of requirement or accident. This is a good plan where the houses are close, together, and for convenience in stoking; but this system is faulty when the houses are scattered and situated a long distance from the boiler, and where early forcing is practised. Two powerful boilers heat the whole of the structures under my charge, some nearly 300 feet away and containing between 9000 and 10,000 feet of piping, one boiler usually being used. I find them anything but economical in the earlier months of the year. Where so many pipes are underground there is a great waste of heat and fuel; in early forcing, when a cold frosty night is succeeded by a bright day, and the fires are stopped early, it takes much hard firing to get the pipes warm again by nightfall with such a large volume of water to heat, and wasting itself in a great measure underground. Again, with such a complication of valves, and various levels of pipes, it is extremely difficult to regulate the heat with any degree of precision. At times it seems inclined to rush in one direction,

FIG. 13.—ZYGOCOLAX VEITCHI. (See page 94.)

at others just the reverse, and it needs the greatest caution when going the last round at night to leave everything safe. Perhaps the attendant may find it necessary on his last journey to turn a little heat on certain houses when there is prospect of a sharp frost, when a rush of cold water into the boiler takes place and the heat robbed from houses where most needed, and failing a bothy on the premises or a night stoker this is most inconvenient.

Forcing houses are more satisfactorily managed when they are heated by boilers fixed at the back or north side of them, presuming they have a southern aspect, which all such houses should have. By this system the heat can be more quickly circulated and also shut off, than when it has to be conveyed a long distance by one large solitary boiler with numerous connections, for this entails a waste of fuel in heating a large volume of water, probably early in the season, for one or two houses only. A smaller boiler close by performs its work more efficiently and economically.

### ARRANGING HOT-WATER PIPES IN FRUIT HOUSES.

In arranging hot-water pipes for fruit houses, the first thing to consider is what occupants are to be grown therein, and what degree of temperature will be required to cultivate them successfully; whether the houses are required to produce ripe fruit early in the season, or at a later period when the sun's rays gain more power, for according to their requirements so are the houses constructed for their various purposes, and the amount of piping regulated likewise. We will take an early vinery from which ripe Grapes are expected by the end of May. For this purpose the lean-to form is undoubtedly the best, and such houses are usually erected against walls. That this form is best is obvious, as it

receives every ray of sun, which is of great importance in the early part of the year.

With respect to the amount of piping required, we shall have to consider the dimensions of the house. The usual size for early vineries is about 40 feet in length, 14 feet high at the back, the same in width, and 3 or 4 feet high in front. For efficiently heating a structure of these dimensions, six rows of 4-inch pipes the whole length of the house, and two rows at each end would be required. The vineries I have are larger, and have eight rows of pipes, which gives 1 foot of radiating surface to about 16 or 17 cubic feet of air. This we find quite sufficient. The dimensions previously given would average about the same proportions. It is far better to have a sufficient amount of piping moderately warm than a less amount which during severe weather has to be highly heated, producing anything but a congenial atmosphere. The flow pipe will be connected with the main at right angles, another connection rising from this into the house by the inside of the pathway.

Here I would point out the error of introducing the latter pipes at too great a height vertically from the first connection. I have them rising 5 feet, and at times the greatest difficulty is experienced in getting the heat into such houses, probably from friction at this junction, the heat invariably flowing to the easier gradients, and also leaving these points when there is not much pressure. It would be better if the connections from the main were brought into the house by an easier gradient. Such pipes should never have such a stiff rise, especially close to a number of connections, neither should flow pipes be arranged so that they have to dip under pathways and be fixed at a lower level than the returns until they rise again into the house, as the circulation is then never satisfactory. It might answer, but it is not the correct principle to work upon.

Where the pipes enter the house, good air-tight screw-down valves should be fitted on both the flow and return. There are various ways of arranging these six pipes. Sometimes four flows are taken along the front wall, converging into two single pipes at the other end of the house, forming the returns, which are carried alongside of the pathway on a parallel with the flows, and are connected with the main return. Air pipes should be fitted at the highest point of all flow pipes. At other times the pipes are arranged at equal distances over the floor of the house. In some instances one flow pipe is taken along the front wall and around the other end of the house, another 5 feet from it and parallel with it, joining it at right angles. These two are then converged into a single pipe. Then, supposing a tank was erected at the incoming end, which prevented the return being carried through into the main, we should have to continue the single flow pipe as far as the tank, bring the return back underneath it to the point where the two flows meet, where they are continued in a corresponding manner to the flows (underneath them), and on reaching the end of the house are connected into a single pipe and join the main return. This is not a good plan, and only adopted when unavoidable. Or we will suppose that two flow pipes are taken from the pipe entering the house and are carried along the front wall, two more flows 5 feet from them, and on a parallel with them, are carried to the opposite end of the house. These two sets of pipes here converge into two single pipes forming the returns, which are carried back 9 or 10 feet from the front wall and parallel with it, and connected into a single pipe into the main. This last-named system is undoubtedly the best, for the heat circulates quickly and equally, which early in the season is important. Sometimes the pipes are arranged similar to the above, commencing 18 inches from the front wall. Either plan will answer. I have never seen that it made any material difference. In any case the pipes should be arranged near the surface, for heated air ascends, and if fixed higher a portion of the heat is lost.

Evaporating troughs should be cast on some of the pipes, and arranged at equal distances apart. These should be five in number, 6 feet in length, and 6 inches wide. It will be necessary to form brick piers on a solid foundation at every 9 feet to carry the pipes, which may be packed upon these or carried on short iron standards. Slate cisterns for holding water should be provided in all such houses, and heated with a coil of 2 or 3-inch pipe, this being connected with the flow and return mains with pipes of less diameter, and fitted near the tank with stop-taps. These pipes ought to be independent of any required for heating the house. Houses are often built without regard to this matter, but it is a great mistake. The pipes should be painted black, this being best for radiating heat; and the mixture for the purpose generally used after they are in working order is boiled linseed oil with just enough lampblack to colour it; if too much of the latter is used it rubs off. The pipes should be made slightly warm when applying the mixture, and not be coated too thickly, this preventing radiation. The troughs should be painted red to preserve them, which also gives a smart appearance to the house. All joints of pipes must be effectually packed. Some use indiarubber rings, and fill in with cement; others use spun yarn and red lead; but the first-named method is the quickest and best if properly done. Joints near the fire should be made with iron borings. The above conditions apply to such Grapes as Black Hamburgh and the like. Muscat of Alexandria would require rather more piping if forced early. In the north of England this fine Grape should be cultivated in lean-to houses.

#### PEACH AND OTHER HOUSES.

For the early forcing of Peaches a house of similar dimensions would be suitable, only a less amount of piping would suffice. Four rows of 4-inch pipes the whole length of the house and two rows around the

ends should be employed. These may be arranged by bringing a single pipe from the main and connecting two flows; these ought to be continued along the front wall to the opposite end of the house, then they will descend by the side of the pathway, joining the main return in a corresponding manner to the flow. This amount of piping gives 1 foot of radiating surface to about 24 cubic feet of air. Valves, of course, should be fitted on both the flow and return where they enter and leave the house. Both valves in such positions must always be regulated equally, otherwise it is apt to derange the circulation. Sometimes single pipes are arranged continuously at equal distances over the whole of the floor of the house—half forming the flows, the rest the returns. If heated by a small boiler especially for the purpose, often without valves, this is a most objectionable system for several reasons, space not allowing explanations. Evaporating troughs will be needed according to requirements.

Fig houses, for producing early fruit, should be of the same proportions as for Peaches, but half the length would suffice; for, as a rule, they are not in such demand as the preceding fruits. They require similar treatment to Peaches with regard to temperature, therefore the same arrangements of pipes would answer.

Succession houses would require the same number of pipes—one less might answer in some localities, but it is far better to have enough than to find out at some critical period there is no possibility of keeping the temperature up. If houses are of different dimensions to these given, the heating power required can be ascertained by calculating by the same ratio, or other means will suggest themselves.

Cherry houses, if as large as those previously named, would require a similar amount of piping if the trees were forced early. In warm localities two flows and one return might answer, high temperatures not being necessary.

Late vineries and orchard houses are often constructed in the span-roof form, running north and south. For summer culture this form is best, as they contain a large volume of light and air. The east side gets the morning sun when at meridian its rays strike the top of the roof and south end, while the west side get the afternoon sun.

The span-roof vineries under my charge are 40 feet long, 24 feet wide, 13 feet high at the apex, and 4 feet high at the sides. These are heated with ten rows of 4-inch pipes. For late Grapes requiring plenty of heat I find they do not give too much heating surface. The flow pipe on entering the house branches right and left to the sides; these are continued along the wall on each side until they reach the opposite end, and then return parallel with the flow 9 feet from it. Two more flows are connected at right angles to the incoming flow pipe, 5 feet from the front wall, and are carried to the other end of the house, where they are connected into a single return pipe, which runs side by side and parallel with the other return. These, when they reach the end of the house from where they started, are connected into a single pipe into the main. Flow and return 2-inch pipes are carried under the pathway from the mains for the purpose of heating the cistern at the end of the house.

For houses containing such Grapes as Black Hamburgh eight rows of 4-inch pipes would be enough. Two flows along the wall, continued around the opposite end, and, returning on a parallel with, and 9 feet from them, back into the main return.

Span-roofed orchard houses will need a flow and return pipe on each side of the path, arranged singly on the same principle as the above. If lean-to a flow and return will suffice, the flow taken along the front wall, returning by the inside of the pathway, these structures only needing protection from frost, and a little warmth if necessary to ripen the wood of the trees.

Pines I have left until last, these not being largely grown nowadays. A fruiting house of useful dimensions would be 30 feet long, 16 feet wide, 9 feet high at the back, and about 4 feet high in front, of course built in the lean-to form. A chamber should be constructed about 3 feet from the back wall, and may be 21 feet long and 8 feet wide, heated with four rows of 4-inch pipes. Another path should be constructed along the front of the chamber 3 feet wide, and this would allow of a small pit or stage at the front of the house, which could be utilised for many purposes. If the front chamber is not desirable it can be dispensed with. This arrangement allows of every convenience for attending to the plants. For heating a house of this kind six rows of 4-inch pipes would be necessary. Four rows along the front, two flows and two returns, the remaining two pipes, one flow and return, being arranged along the back wall. Valves must be fitted on both sets of pipes, the flow and return pipes from the main being brought into the house transversely to these. Succession houses could be of the same dimensions. For suckers and small plants any ordinary forcing pit would answer. Sometimes fruiting houses are built about 8 feet high at the back and 11 feet wide, the path at the back, the bed in front, but this is a very inconvenient arrangement unless the lights are moveable.

#### BOTTOM HEAT.

Forcing houses with bottom heat are generally understood not to contain permanent occupants, but are utilised for forcing various kinds of produce as required, such as Melons and Cucumbers; also for forwarding flowering shrubs and plants. These should be lean-to with a southern aspect. As a rule they are too large for the majority of places. I consider a house 20 feet long large enough, thus a better succession can be maintained and a glut avoided. A house of this length ought to be 6½ feet high at the back, 2½ feet in front, and 10 feet wide. Houses of this description are usually built partly sunk beneath the ground level. Four feet in width should be allowed for the chamber in

front, which ought to be heated with three rows of 4-inch piping, 3 feet allowed for the path, and a narrow chamber at the back. It will require four rows of 4-inch pipes to heat such a house, a flow and return along the front, a similar arrangement along the back wall. Valves must be fitted on both sets of pipes. If a number of such houses are wanted a range can be divided by partition. The bottom-heat pipes are usually covered with slates, supported by iron bearers at about 18 inches from them. For summer culture houses may be constructed span-roofed, 9 feet high, 11 feet wide, with chambers on each side of the path 3 feet wide and 3 feet deep, heated with two rows of 4-inch piping, a flow and return on each side for top heat.

Houses for forcing Strawberries are not usually met with, these being brought along in such structures as the above, a temporary stage being erected, and the heat regulated to suit their requirements. If such a house should be contemplated, then it may be a little higher at the back, a stage erected with a slope towards the front, where the path would be constructed, as being more convenient for reaching the plants, and heated with two 4-inch flow pipes along the front, the return taken along the back, no bottom heat being required—at least, it is not actually necessary. A house 20 to 30 feet long and 10 feet wide would answer the purpose well.

One important structure, which singularly is generally found wanting in gardens, is a good propagating house. The dimensions given previously for lean-to forcing houses will apply here, the chamber being a little wider in front, reducing the other at the back. This should be constructed so that the small plants may be kept close up to the light, and still benefit by the heat at their roots. Four rows of bottom heat pipes would do better here, and anyone having much propagation to do, or raising early Melons and the like, will recognise the importance of this necessary structure.

#### THE MANAGEMENT OF FIRES.

Something must be said on fires and their management. The question of fuel greatly depends upon the position of the locality, the best being that suitable for the furnaces, combining efficiency with economy. Gas coke is probably more employed than any other. This is better for upright tubular boilers, coal or large coke not being so suitable, as it is liable to bind, and remain in the upper portion of the boiler after combustion has taken place below. Large hard coke is often used for powerful saddle boilers, and when there is a good draught this produces a great heat, does not clinker much, and there is little waste. This is obtained by burning slack and small coal in large ovens specially for the purpose. This is the kind of fuel we use, and we find it very satisfactory. Of late years anthracite coal has become much used. This gives more heat than coke. Sometimes coal and coke are mixed together. The fire should be spread evenly over the bars so that the whole of the surface exposed to the fire may be heated, not heaped up in one place, and the fuel added in sufficient quantity to always keep the fires bright, except when they are stopped, not in large quantities at one time. The bars and flues must be kept perfectly clean, with sufficient draught top and bottom to produce combustion. The dampers should not be opened more than is necessary for this purpose, otherwise the heat is wasted up the chimney.

In regulating temperatures judgment must be exercised with respect to the weather, this being the chief factor in managing the heat satisfactorily. When likely to be bright the heat should be reduced early, and the fires stopped, starting them early enough to get the pipes warm again by nightfall, or as may be required, executing the work in the most economical manner.

Strong valves should be fitted on the mains where they branch in various directions. Also 1½-inch pipes must be brought from the end of the boiler into the stokehole to empty the same if required. I omitted to mention that midseason houses may be constructed on the hip-roofed system if circumstances render it desirable, as affording a great abundance of light. When constructed against south walls ventilation is often provided for on the north side. The cold winds coming in that direction, especially early in the season, cause a great depression in the atmosphere, when it is found necessary to open the ventilators to any extent, and I am of opinion it should be arranged on the south side. The amount of piping necessary under ordinary conditions would be as advised for lean-to structures.—J. J. CRAVEN, *Allerton Priory Gardens, Liverpool.*

#### FUNCTIONS OF VINE LEAVES.

MR. BARDNEY, on page 525 (December 15th, 1892) contrived to condense the whole controversy into a nutshell, and he could not have better expressed my views had he been commissioned to do so. To me it was very satisfactory to find that he has modified his views considerably in the matter of allowing Vines to form a superfluity of wood. Plenty of men there are who also alter their views on different subjects, but have not the courage to confess as much. He rightly makes a distinction between Vines in good health and those requiring to be renovated, and that is what all should do. If the root action is defective, allowing more leaves to develop is one of the means of restoring the balance, but there is no sense whatever in permitting Vines to expend their superfluous energies in the formation of foliage or wood that only interferes with their other functions.

Mr. Bardney is evidently of the same opinion as myself regarding the value of extra large leaves. I have seen too many instances of the comparatively worthlessness of rank foliage and coarse growth to envy my friends their achievements in that direction. Give me medium

sized perfectly healthy leaves and wood to correspond, the latter, whether in the shape of young shoots or short spurs, being far more durable than any of a grosser character, and will produce the most perfect if not exactly the largest bunches. Then, late-formed foliage is worse than useless, and all that is needed are enough primary leaves to afford a thin canopy for the bunches. Two good leaves beyond the latter and other laterals not bearing bunches and of much the same length are ample, and if the foliage is kept clean and sound, the roots properly supplied with moisture and food, and overcropping avoided, there will be no renovating measures needed for very many years.—W. IGGULDEN.

THE NATIONAL ROSE SOCIETY'S FIXTURES.

THIS promises to be as fruitful a source of *arguifying* as I remember the word *Gladiolus* used to be in a certain horticultural society with which I was acquainted. Whenever they were at a loss for something to talk about someone would mention the word. Then arose the question, Was it *Gladiolus*, *Gladiolus*, or *Gladiolus*? The discussion used to be prolonged, somewhat classical, and earnest, but I believe the result was that everyone held to his own opinion, no way altered by what many thought the conclusive arguments put forward; and I think it is likely to be much the same with the fixtures of the National Rose Society, more especially the metropolitan one, and I do not suppose that anything I may write will have the least effect upon any of the disputants; but for all that, as one or two letters have appeared lately on the subject which seem to require notice, I venture to "take off my coat," and enter the lists.

In discussing this subject I think I have some advantages over many if not all of those who have taken part in the controversy. In the first place as Hon. Secretary of the National Rose Society I know all about its position, its requirements and its difficulties, and there are many things which many of your correspondents seem to be unaware of; and then in the second place I am not an exhibitor, and this is I think a very great advantage. Not one, even officers of the highest rank, who were engaged in the strife could have had so clear a view of the great fight of Konigratz as Dr. Russell, when from the top of the tower he had the whole laid out before him. Those engaged in it could only take in the part immediately around them. So it happens in such discussions as these the writer is evidently influenced by the circumstances of his own garden, and hence his judgment is not altogether a disinterested one. The non-exhibitor can certainly, like the non-combatant, take things more easily.

There are some things of which many of your correspondents seem to be ignorant. It must always be remembered when some write so loftily of arrangements, and what should be done and what not, that we are not independent, that we are quite dependent on the Crystal Palace Company for having any Metropolitan Show at all. It may be a humiliating confession, but it is true for all that. We have made attempts to act independently, but failure was the result. Our first Exhibition entailed a loss of some £200. We have sought in vain to find any place fit to show Roses in, but there is none. Moreover, an Exhibition could not be got up in London under at least an expenditure of £400, and our experience at St. James's Hall was that we did not attract half a dozen of the passers by, those who did come were persons more or less connected with the exhibitors. Consequently, while it answers the C.P. Company to have the Exhibition there it unquestionably answers ours, although there are disadvantages. Thus the matter of arrangements must depend on them, not on us; but I am bound to say some persons have very short memories. It is only now and then that we are interfered with by such a matter as the Electrical Exhibition, and very rarely that our exhibitors have to complain of want of space; in most of our Exhibitions both we and Mr. Head have had to complain of great gaps being left, because exhibitors have not brought their stands, and have given no notice of their withdrawal. Again, it strikes one as a very idle matter to compare the arrangements of a great Show at the Crystal Palace to any provincial one, however good. In the latter you are confined to one tent, and you can get to any part of it in a couple of minutes, not so at the C.P., as many know to their cost. If an amateur is exhibiting in the amateur and open classes he has often a long way to traverse before he gets his plants staged, and considerable delay is also made for the same reason in uncovering the boxes and getting the blooms ready for the judges. I hope that the Committee will see their way to appointing someone who will have nothing else to do but to see this part of the day's work carried out, and who will have authority to have all lids removed in time for the judging. Personally, I cannot do it, there are so many things about which I am continually badgered that I cannot undertake this. Here is one angry exhibitor who, on being asked to clear out, folds his arms and steadily refuses to do so until he gets a place for his box; here is another who wants to know whether he is to put his box in such a place as that; while the mistakes of exhibitors who in their anxiety place wrong cards upon them only increases the confusion.

With regard to the date for the Metropolitan Show I have been

intensely amused at the virtuous claims put forward by some. One writer, with most refreshing *naïveté*, suggests that those who advocate the early date have only thoughts of their own Roses, evidently assuming that the dear innocents who favour the later date were no way influenced by such motives. And yet one could not help smiling, for did we not know that the gravamen of some of the doughtiest champions was that only flowers from cut-backs could be shown, their maidens not being in, and all the while thinking of them they were humming to themselves "The Girls I Left Behind Me." Again, some of these advocates of a later date are very susceptible about the dear northern growers, but I think we may well ask who they are? Since the retirement of Mr. Whitwell and Mr. T. B. Hall we have no amateur grower of the first class in the North, and very few of any class. We have in the Midlands a few, but they have yet to make their mark. It is the same with regard to professionals. Setting aside Messrs. Harkness and Mack, the latter a very rare exhibitor, we have none, and Messrs. Harkness having now taken some land at Hitchin may be almost regarded as southern growers. Nor do I find that the susceptibilities of the northern growers are much taken into account at the provincial Exhibition, for since Mr. Hall's days the Jubilee trophy and most of the principal prizes have gone to Essex, Somersetshire, Gloucestershire, Hertfordshire, &c., so that it is raising a false issue to put forward the northern growers as a reason for altering the date of the Metropolitan Show. Mr. Grahame has put the matter clearly, and I think that these additional facts ought to have some weight.

The same airy indifference with regard to the real circumstances of the case pervades the statements of those who find fault with the judging, and suggest methods for its improvement. Do the writers quite understand how it is? In the first place, then, look at the time. Even if the exhibitors kept their time we should have but an hour. The space is cleared, or ought to be cleared, for the judges at eleven o'clock, and at twelve o'clock the holders of private view tickets and the season ticket holders of the Crystal Palace are clamouring for admission, and must be admitted; hence it is impossible but that there must be, in some instances, hasty judgments. I do not say that they are therefore wrong, but they are hasty. Then, again, do exhibitors understand that there are upwards of sixty judges required, and I think it will not be speaking too severely to say that there must be some inexperienced ones amongst them. The notion, then, put forward by some writers with regard to the medal Roses that they should be judged *after* the other classes are judged is deliciously absurd. The driving of six omnibuses abreast through Temple Bar would be child's play to such an attempt as this. I have been more than once called very hard names because I would not prevent the visitors after twelve o'clock from putting their unwelcome presence amongst the judges. And while writing on this subject I would emphasise most strongly what I cannot but think must be called the inconsiderate conduct of some of those who are selected for the office of judge; they accept it and then never turn up. No one but the unfortunate Secretary can have any conception of the amount of confusion and trouble that this occasions, and the disorganisation occasioned by it is one of the most fruitful sources of complaint. I most sincerely hope that all who accept this post in the present year will not allow anything to interfere with the fulfilment of their engagements. When especially this takes place in the higher classes, where the judges have been most carefully selected, the confusion that this creates has not reference only to the class from which the judge has dropped out, but in others from whence one has to be taken to supply his place.

The subject of voting by proxy is one with which I confess I have no sympathy. It has been abolished in our highest legislative assembly, it is not used in any public body that I am aware of; it is true it is adopted in railway companies, but that is of an entirely different character. The questions to be submitted to the annual meeting may be taken in various aspects, and so may the reasonings of those who take part in the meeting. I remember once being with a friend who was to preach for a special object at a church in Sussex, but before the sermon was preached the collection was to be made. Never shall I forget the indignant scorn with which my friend, who was an Irishman, replied to the churchwarden: "And do you mean to tell me that, no matter how eloquent I may be, it will make no difference in the collection?" I need hardly say it damped his appeal, so if members send their proxies it would imply that their minds were made up, and that no force of argument would in the least degree affect the decision; thus it would entirely destroy the character of our meetings, on which we have been so often complimented. However strongly members may feel, they speak with forbearance, and I have never seen anyone lose their temper except once. Then it brings rosarians together, and this is a great gain.

With regard to dates for shows, it should be remarked that taking the challenge trophies as a test in the ten years, from 1881 to 1891, the amateurs' trophy has once been taken by a northern grower, Mr. Whitwell, and the nurserymen's twice by Messrs. Harkness & Sons; while the Jubilee trophy, which it was certainly hoped would be taken by northern growers, has twice out of the four times been taken by Mr. Pemberton, and the nurserymen's twice by Mr. F. Cant. These facts I think sufficiently prove that it is impossible so to fix dates as will meet both north and south alike, and that the fairest way is to consider the southern growers in the metropolitan shows, and the northern and midland growers in the provincial shows. It is the same in other societies. It was impossible to fix a date for Auriculas that would suit both northern and southern growers, so there was a separate date fixed for

each. I have often heard my friend Mr. T. B. Hall say that the best Roses he exhibited during the season were those set up at the Liverpool Show towards the end of August, and I feel assured that there are so many things that influence the Rose—soil, situation, the stocks used, and the character of the season, that it will be always impossible to fix a date that will satisfy all, and that taking all this into consideration we can hardly improve on the present fixtures.—D., Deal.

P.S.—I wish it to be distinctly understood that in the foregoing observations I do not write in my official capacity, but simply as a member of the N.R.S.

#### NATIONAL ROSE SOCIETY.—JUDGING.

IN reply to "W. R. Raillem's" remarks (page 70) on judging I would like to explain my meaning. I have no doubt "W. R. Raillem" will more readily agree with what I now say, but I thought that my former remarks would be understood, although not expressed to the fullest extent. There are many of our largest amateur growers who also exhibit, but the work of observation is done by their gardeners. Many of these gentlemen are rosarians by courtesy, but not so in reality; and "of such" are the large growers I referred to! I abide by my previously expressed views, that a small grower—a person, for instance, who grows 100 exhibition varieties, say six of some and as many as eighteen of others, and who, taking account all round, is a grower of about 1000 or 1500 Roses, who has these Roses well within view; who also has the plants so arranged that some have cool positions and others warm early corners, &c; such a rosarian, by knowing the habits of Roses grown in various positions, by seeing other persons' exhibits, and by being a man or woman of observation (I have a very high opinion of the discrimination of ladies in Rose culture and exhibiting) can be a judge of the very highest class. After all how many varieties are constantly shown? I venture to say not nearly 100; no, not even 60 varieties. Of course, in the seventy-two champion nurserymen's class there may be some half a dozen Roses not frequently seen, but they are not the blooms on which the result of the championship usually will turn.

I cannot see what the question of the *soil* of the gardens the Roses come from has to say to the value of the Roses set up—you judge the Roses, not the soil, and the same applies to the moss. I do not think a judge should give a single point to the moss; he is placed as a judge over Roses, not moss, and he should judge the flowers individually as well as collectively; if they be superior to their opponents in quality, and the setting up in no way infringes any rule of our Society, then they should be awarded the first place, and I am sure that our judges do make their awards on this basis. I also think that any doubt of such fairness on our part as judges would deter new members from exhibiting, especially as young rosarians must be only too conscious of their shortcomings in setting up and other details only mastered by constant practice. I shall defer the discussion of the Metropolitan Show to the autumn, I should like to say to the Greek Kalends.—CHARLES J. GRAHAME.

P.S.—In connection with my assertion of the number of varieties most frequently shown at exhibitions, I would refer your readers to Mr. Mawley's article on this subject published in the Journal some months ago.—C. J. G.

#### PROXY VOTING.

I do not quite follow "K." (page 70) in his remarks upon this question. Of course it is more satisfactory to vote in person, but we contend that it is better to vote by proxy than at a heavy cost of time, money, and trouble, which in these days too often means not voting at all. I and others have "pegged away," but the expense and sacrifice of time have been, as I expected, too great for all but a few. Besides, the distant members think they have not their share of privileges in other respects, and so they are scanty in number and lukewarm, not hearty and united enough to make their voice heard as a strong body. They know that they would be "at a disadvantage" even in voting by proxy, but they are strongly of opinion that they are at a worse disadvantage as at present situated.

In money alone it costs a large average of the distant members as much as their yearly subscription to attend and vote; why should they be charged twice as much as the metropolitan members for the privilege of voting, when they will still be at a disadvantage in matters of climate and date? I am sure the N.R.S. should for its own sake justify its title by endeavouring to show equal justice to the members at a distance.—W. R. RAILLEM.

#### THE DATE FOR THE "ROSE DERBY."

AS prominently connected with the question of the date of the Metropolitan Exhibition of the National Rose Society, now being so vigorously discussed in the gardening papers, may I be permitted to offer a few remarks and a friendly criticism?

We must not individualise. It is not a question of what date suits Smith, Jones, or Robinson. We must take a broader view than this. The case for the later date rests principally on these grounds. 1, The Society claims to be "National." 2, The Metropolitan Show is the "Rose Derby" of the year. 3, The "Rose Derby" should be held at the height of the Rose season of all England, not a small part of it, for the Society is "National." 4, The "Rose Derby" this year is fixed for July 1st. 5, Can either July 1st, 2nd, or 3rd be considered the height of the Rose season?

If the most popular dates, if the dates on which there is the greatest clashing of Rose shows be any criterion as to the height of the Rose

season, then, from a return based on the last eight years, July 8th and 9th are the most popular dates, more shows clashing on these dates than on any other, and, therefore, presumably the height of the Rose season. I have exhibited at every "Rose Derby" from the first Show held in St. James' Hall in 1877, and my experience leads me to the same conclusion—viz., that the height of the Rose season is July 8th or 9th.

Now for a little friendly criticism. What special advantages does Mr. Grahame possess whereby to form his opinion as to the height of the Rose season? 1, Has he a lengthened experience? No. His name first appears as a member of the N.R.S. in 1889. 2, Has he a large Rose garden, growing plants in different situations? No. He describes his garden as "being of the most diminutive size." 3, Does he grow his Roses in such a way as to lengthen his Rose season, cut-backs followed by maidens? No. He says in reference to maidens, "I have no room to try such experiments." 4, Does he visit, other than the two provincial shows of the N.R.S. in 1891 and 1892, the Rose shows north of the Trent, and so ascertain the high standard there attained in the latter half of July? No. He says, in reference to attending these shows, "I am not anxious to compete out of my proper district." Herein, I think, lies the reason for the course he has taken. If his "proper district" was less circumscribed, if he ventured once now and again to visit northern shows, he would know the strength of the north. He would know on what date the northerners are at their best. He would not class Messrs. Burch of Peterborough with "other northerners," seeing Peterborough is seventy or eighty miles south of Worksop. He would know that the Midlands, except in special localities, is the latest of all districts. He would know the "Cants" do not show north of the Trent "late in the season." He would know the grand displays of seventy-two blooms exhibited at the late shows by Messrs. Merryweather, Harkness, Perkins, Dickson, and Cocker; he would remember, if he had been there, the magnificent Charles Lefebvres exhibited by Mr. Machin last year on July 30th; and when he knew all this he would desire to see such Roses exhibited at the "Rose Derby" of the year.

I am sure he will take my criticism in good part. A difference of opinion should not make us worse friends; but I cannot forbear speaking my mind when I observe him stating time after time that which I feel sure he would be the last to state were he not drawing upon his conjecture rather than speaking from experience.—JOSEPH H. PEMBERTON.

#### DOUBLE PRIMULAS AND THEIR CULTURE.

THERE are many good forms of Primulas in cultivation. I have grown a variety named albo-pleno fimbriata for many years. It is invaluable for supplying cut flowers during the winter. Nurserymen and florists are alive as to the value of these plants for supplying a profusion of choice white flowers. In visiting a nursery where there are large demands for cut flowers one would be astonished to see the number of double Primulas grown for that purpose. Many people find it difficult to propagate and grow these plants satisfactorily. I grow from eighty to 100 of them annually, and will now give a few simple cultural instructions that I have proved to be sound.

After the plants have done flowering I clear off all the bottom leaves. I then prepare some light compost of leaf mould, old cocoa-nut fibre refuse, silver sand, and crushed charcoal. With this material I earth the plants up, forming a mound around the stems, but not entirely covering the crowns. After this they are watered through a fine rose to settle the soil. They are then placed on a shelf in a warm house near the glass, keeping the soil moist by sprinkling the plants in bright weather. Here they usually remain for five or six weeks, by that time they will be well rooted. I then shake the soil from the roots, and divide the plants into as many pieces as possible. Nearly all those crowns can be taken with roots attached. They are then placed singly in small pots in a compost of good turfy loam, leaf mould, a good sprinkling of crushed charcoal, and some coarse silver sand.

After being potted the young plants are placed in a cold pit kept rather close till the young crowns are established in the pots. When well rooted the plants are placed in 48-size pots, in which they flower. The compost for this potting is the same as that recommended, with the addition of a little bonemeal. Careful watering is always needed in the culture of double Primulas, with constant attention from beginning to end, or failure will sure to follow. The best place for flowering them is a shelf near the glass in a warm greenhouse where they will continually produce trusses of bloom in great abundance all through the winter. Are the flowers of White Lady superior to those sent?—E. H., *Mountains, Hildenborough*.

[Admirably grown specimens of a bold form of the old Double White accompanied this communication. The variety resembles a pale form of Annie Hillier, the stems or stalks are of a pale green hue, and the fully developed flowers tinged with flesh colour. White Lady has dark foliage and reddish stalks, the flowers more double and purer in colour, in fact a good white. Marchioness of Exeter is of the same character, but has larger flowers that are less pure. Still, when well grown it is a splendid variety.]

I CANNOT but think Mr. Gilbert (page 75) is under some misapprehension with respect to the names of his double Primulas. I have always understood that Mrs. A. F. Barron was of a carmine colour. It was by that name shown last October, in excellent condition. The white form described by Mr. Gilbert reads like White Lady. Marchioness of Exeter should be carmine flaked, but there is always a tendency for the flake to wear out, and unless plants that maintain that

feature in the flowers are chiefly propagated the flake may disappear altogether. Generally it is of so trifling a form that it rarely interferes with the classification with the white variety. Added to those named, Annie Hillier, robust grower, flowers white, heavily suffused with pink, having also pale green foliage, is good; so also are Rubra grandiflora, crimson; and Atro rose-plena, deep crimson. Those named constitute probably the finest half dozen of double Chinese Primroses in cultivation.

I should like to hear whether anyone has the fine varieties that some twenty-five to thirty years ago were raised by Mr. Stewart, gardener to Mrs. Eyre Crabbe, Southampton, and named and introduced by Mr. Henderson of Pine Apple Place. It is possible that these were not so robust as were those Mr. Gilbert of Burghley put into commerce; or no one may have understood how to grow double Primulas as Messrs. Cannell & Sons, who do them splendidly, or some of the Leatherhead gardeners, whose fine plants I referred to in the late autumn.—A. D.

#### PEAS AND CABBAGES.

NEW varieties of Peas come upon us in such numbers that it is impossible to keep up with them; but it is possible to try two or three of the newer kinds. Gradus is a decided advance upon the early varieties, having pods and peas of the size of the midseason kinds, such as Telegraph. This will be in great request by exhibitors for early work. Handsome though it be, it will not displace Charmer with me, which comes in about the same time, is a heavy cropper, and of excellent quality. Oracle is a great acquisition, a very prolific cropper, bearing its pods in pairs, which are of deep colour, long, and very closely packed. Alderman is one of the giant-podded varieties, and will be a favourite with those who are admirers of immense pods. It is a grand exhibition variety, but I prefer Autocrat, which I believe cannot be beaten for appearance, quality, and cropping. No Pea has ever done so well with me.

I do not like a Pea that does not keep the pods well filled. However young one may pick Charmer, Autocrat, or Oracle the pods are filled in proportion to their size. Some of the giant-podded Peas are too often deceptive in this respect. I am not fond of the very early round Peas, and am quite content to wait for William Hurst, which is early and of excellent quality. William Hurst, Charmer, Oracle, and Autocrat, together with Duke of Albany, form an excellent succession of good Peas such as can hardly be beaten for cropping, appearance, and quality.

#### A TRIO OF CABBAGES.

Last spring I had under trial Ellam's Early grown alongside of Messrs. Vilmorin's Express, Etampes, Paris Market, and Rennes. Ellam's once more took the lead, and had firm little hearts a week before Express, which, however, is a very good Cabbage indeed and a capital companion to Ellam's Early. Paris Market and Etampes I will only say were very good Cabbages, but as earliness is everything I do not think they are desirable when the two first mentioned are obtainable. For a main crop and a large Cabbage of very good quality I can recommend Rennes. This I should judge to be just the Cabbage for cottagers and market growers, for it is by no means slow in turning in, and is of good appearance, compact, and of fair size. It is also good in quality when cooked. These three Cabbages will afford an excellent succession.—H. S. EASTY.

#### LABELS IN KENSINGTON GARDENS.

I SHOULD be much obliged if you will kindly inform me how the names of the plants are written on the large labels used in Kensington Gardens. The labels appear to be ordinary wooden ones painted white and written on with some sort of ink or paint in a bold copper plate handwriting with some very broad pointed pen, and seems to be practically indelible. I should have said such labels were in use last summer, and no doubt are so now.—H. E. M.

[We received the foregoing letter last week, and replied to it briefly in our "Answers to Correspondents." In the meantime we wrote to Mr. W. Browne, the Superintendent of Hyde Park, and he promptly favoured us with the following reply:—

"The labels referred to are 'home made.' I send herewith a couple for your inspection. You will observe they are simply pieces of deal, painted with three coats of green colour, and the points tarred. The name is written in ordinary white paint, with a 'writer's pencil' (small camel hair brush). Labels are a great disappointment to a plant border, reminding one of cemetery tombstones in miniature. I suppose they must be regarded as a necessary evil. However, I think the green ground of our label is a great improvement on those with a white surface."

It appears that "H. E. M." was wrong in his impressions. The labels are not painted white and the names displayed in dark letters, but the labels are green and the lettering white. There is nothing conspicuous about these labels but the names, and that is exactly what is wanted. With white labels the reverse is apt to be the case—the labels obtrusive, and the names obscure. The change is a simple one, but altogether satisfactory, the labels being far more agreeable in appearance than the "staring" white ones that adorn the borders in many gardens. The samples sent by Mr. Browne are made of half-inch deal, one of them 18 inches long and 2 inches wide, the other a foot long, and 1½ inch wide. The names are very clear as represented in what may be termed half-inch letters.]

**EVENTS OF THE WEEK.**—The annual general meeting of the Gardeners' Orphan Fund, for the purpose of adopting the Committee's report and the election of orphans, will be held at the Cannon Street Hotel, E.C., at 3 P.M. on Friday, February 3rd. On Tuesday, the 7th inst., the members of the National Amateur Gardeners' Association will hold their annual meeting at the Memorial Hall, Farringdon Street, E.C., at 7 P.M.

— **THE WEATHER IN LONDON.**—The weather has been comparatively mild in the metropolis during the past week. On Sunday rain fell during the day, but Monday proved fine, with occasional slight showers in the evening. On Tuesday morning it rained. Wednesday opened fine, and at the time of going to press south-westerly winds are blowing.

— **WEATHER IN THE NORTH.**—With a touch of frost on three mornings, and occasional high winds, the last week of January has been generally dull and mild rather than wintry. Snow fell heavily for some hours in the morning and forenoon of Saturday, heavy rain followed at night, and all had disappeared by Sunday morning. This morning (31st) is showery, with the thermometer at 40°.—B. D., *S. Perthshire*.

— **DEATH OF MR. G. W. BOOTHBY.**—We regret to record the death of Mr. G. W. Boothby, Holme Cottage, Louth, which took place recently. Mr. Boothby was in past years a well-known Rose grower, and an authority on horticulture generally. At the time of his death he was fifty-six years of age. Mr. Boothby was of a genial disposition and unassuming demeanour, and his decease will be much regretted by all who knew him.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—The second annual meeting of this Association will be held on Tuesday evening, February 7th, at the Memorial Hall, Farringdon Street, E.C. The Committee's report and statement of accounts will be submitted for approval, and the election of officers for the current year will take place. Mr. T. W. Sanders will preside.

— **PEAR DOYENNE DU COMICE.**—With us few Pears succeed as pyramids or bushes in the open. The above variety, however, is decidedly the best for this form of culture that we can grow. This is not a Pear soil by any means in the open, it being too heavy, cold, and retentive during the winter and spring. When we have a Pear crop at all this variety produces the most fruit.—E. M.

— **A DELICATE QUESTION.**—An unlooked-for question arose at the meeting of the Crays Cottagers' Horticultural Society the other evening. It was stated that an exhibitor, on one occasion, had taken a prize for Roses, although at the time he had not a Rose in his garden, and the question arose whether it would not be wise and expedient to do, as some other societies do, appoint a member or members of the Committee to visit and inspect the gardens of the exhibitors at the time of the Show, as a safeguard against this kind of fraud in the future.

— **CHISLEHURST GARDENERS' ASSOCIATION.**—At a meeting of this Society, held on the 24th inst., Mr. H. Cannell of Swanley delivered a lecture on "The Rose." He detailed the treatment required, and brought to light many points of great importance in the successful cultivation of the Rose. The Society have only been in existence for about eighteen months, but much good and useful information has been spread by its agency through the locality, and the future bids fair for greater success.

— **PRESENTATION TO A SEEDSMAN.**—Mr. George Thomson, foreman in the seed department of Messrs. Ben. Reid & Co., Guild Street, Aberdeen, who is shortly leaving for Africa, was waited on at his house by a deputation of his fellow employes recently and presented with a handsome dressing-case, subscribed for by the hands in the seed department. Mr. Cook, in making the presentation, spoke of Mr. Thomson's twelve years of faithful service and of the high estimation in which he was held by his employers and their customers with whom he came in contact.

— **RICHMOND HORTICULTURAL SOCIETY.**—We are requested to state that the summer Show of this Society will be held on June 28th next.

— **MR. SAMUEL BARLOW.**—The *Middleton Albion* sheet almanack contains an excellent portrait of Councillor Samuel Barlow, J.P., C.A., who is the Mayor of Middleton, and we are pleased to see the ardent and genial florist looking so well.

— **PROFESSOR MICHAEL FOSTER, Sec.R.S.,** one of the Vice-Chairmen of the Scientific Committee of the Royal Horticultural Society, has been appointed Rede Lecturer at Cambridge for the present term. His Rede lecture will be delivered early in June.

— **ENGLISH WALNUTS IN CALIFORNIA.**—Besides numerous other kinds of fruit English Walnuts are now grown in California. A Californian paper informs us that a single train from Rivera, in Los Angeles county, recently carried East for transportation 200 tons of these nuts.

— **A FRENCH BOTANICAL INSTITUTE.**—The French Minister of the Interior has established at Marseilles, in connection with the university, an institute for botanical and geological research, and a museum. The director is Prof. Heckel, who, as well as a curator and a librarian, gives his services gratuitously.

— **FRUIT GROWING IN CALIFORNIA.**—They do business on a large scale in California. The "Fruit Grower" tells of one firm with 500 acres of Prunes, Peaches, Pears, Nectarines, and Apricots, from which they obtained an average of £52 per acre. The same firm has a vineyard of 1100 acres that they expect to realise at least £40 per acre.

— **BRIXTON, STREATHAM, AND CLAPHAM HORTICULTURAL SOCIETY.**—At the annual general meeting of this Society the date of the autumn Show was fixed for November 8th and 9th at the Streatham Town Hall, and on the suggestion of the Hon. Sec., Mr. W. Roupell, it was resolved to affiliate the Society to the Royal Horticultural Society.

— **A LARGE ROSE TREE.**—At Cologne there is a Rose tree, says "Meehan's Monthly," which is believed to be 300 years old, and has a trunk of 4 feet in circumference. California has one which is now 3 feet in circumference at the ground. It was only planted in 1876, and is now said to cover 2000 square feet. Unfortunately, the variety is not mentioned.

— **THINNING FRUIT.**—A prominent Missouri Apple grower experimented with thinning his fruit on the half of each of several trees to note the effect. On that part of each tree where the fruit had been vigorously thinned, the matured Apples were more than twice as large as on the other part of the tree, of much better quality, and, says an American contemporary, sold for a better price. Not only this. The part of the trees where the fruit has been thinned bore each year, while the unthinned parts bore only on alternate years.

— **PRIMULAS IN AMERICA.**—Our excellent transatlantic contemporary, the *American Florist*, shows by well-executed photographic illustrations the character of Primulas grown on the "other side." Assuming them to represent good cultivation, we cannot fail to notice how inferior the plants are to thousands that are grown by gardeners in this country; nor are the "life sized" blooms depicted in the pages referred to by any means equal to the best English strains.

— **AMERICAN PRIZES FOR NEW PRODUCTIONS.**—From the above source we find that if we excel in the growth of Primulas, our transatlantic friends take the lead of us in encouraging the production of new varieties of fruit, flowers, and vegetables. The Massachusetts Horticultural Society is particularly to the front in this respect. In addition to numerous other awards, special prizes are offered as follows:—Fruits: For the best seedling Apple and Pear, £12; for the best seedling hardy Grape, £12; for the best seedling Cherry, £8; for the best seedling Strawberry, £6; for the best seedling Raspberry, £8; for the best other seedling fruit, £8. Flowers: For the best seedling Rose, £10; for the best seedling Camellia, £10; for the best Azalea indica, £10; for the best seedling Tree Pæony, £10; for the best seedling herbaceous Pæony, £10; for the best seedling hardy Rhododendron, £10; for the best seedling hardy Azalea, £10; for the best seedling Chrysanthemum, £10; for the best seedling single-flowered tuberous-rooted Begonia, £10; for the best other seedling flowering or foliage plant, £10. Vegetables: For the best seedling early Potato, £6; for the best seedling late Potato, £6; for the best other seedling vegetable, £6.

— **NATIVE GUANO.**—The Native Guano Co. (Limited), 29, New Bridge Street, Blackfriars, E.C., send us, through their agents (Messrs. Laughton & Co.), a pamphlet of some fifty-six pages, setting forth the virtues of this valuable manure. A glance at the contents of the *brochure* will convince anyone that native guano is extensively used in gardens. Reports as to its value for producing garden and farm crops, sent by well-known gardeners and gentlemen from all parts of England, Wales, Ireland, and Scotland, are embodied in this publication. Some useful hints as to the amounts that should be applied to various crops are also included.

— **KINGSTON GARDENERS.**—At a meeting of a number of the gardeners of Kingston and Surbiton held last week, it was resolved to form a Gardeners' United Cricket Club for the district, and a code of rules was drawn up and passed. Mr. W. Henbest, Anglesea House Gardens, was appointed captain. After the business incidental to cricket was disposed of, it was further agreed to convene a meeting of the gardeners of the district and any others interested in horticulture, which will be held at the Albany Hall, Kingston, on the evening of the 2nd of February. By special request Mr. A. Dean undertook to convene the meeting, the object of which is to form, if possible, a Gardeners' Association for the promotion of the social and intellectual status of gardeners. It is hoped that there will be a large attendance, and that so important a town will have its Gardeners' Improvement Society.

— **BANQUET OF THE FRUITERERS' COMPANY.**—The Master and Wardens of the Fruiterers' Company are chosen on St. Paul's day, January 25th, and the Lord Mayor is entertained at the banquet. This was held in the Whitehall rooms of the Hotel Métropole, the Court and Liverymen of the Company assembling on the occasion. In the unavoidable absence of the Master, H. Martin, Esq., H. R. Williams, Esq., P.M., ably presided. The Very Rev. Dean Hole, Hon. Chaplain of the Company, was present, and the list of ninety guests, published in the *City Press*, contains the names of Messrs. G. Bunyard, J. Cheal, T. F. Rivers, and J. Wright. The Lord Mayor, H. S. Foster, Esq. M.P., Mr. Alderman and Sheriff Renals (Renter Warden), and the Chairman were the chief speakers, the latter founding an excellent address on the returns he had received from the Board of Agriculture, published on page 74 last week.

— **EDUCATION FOR GARDENERS.**—A correspondent writes:—"There are so many efforts being now put forth to promote wider knowledge of horticulture generally that it is to be hoped special endeavours will be made in the interest of gardeners. It does seem as if County Councils are far from being indifferent to the requirements of gardeners, and in numerous cases have given gardeners' associations the help of paid lecturers. Capital work also has been done through the aid of garden demonstrations during the summer months, and in that direction much more might very well be accomplished were members of gardeners' associations to make it the practice to visit in numbers some of the best gardens, nurseries, and market establishments available, and there have the assistance of competent demonstrators of higher or more excellent garden practice. Such visits as now take place are usually of too pleasurable a kind, and whilst that is good something really instructive would be better."

— **TEIGNMOUTH GARDENERS' IMPROVEMENT ASSOCIATION.**—A PRESENTATION.—At the fortnightly meeting of the Teignmouth Gardeners' Mutual Improvement Association, held on Tuesday, 24th inst., Mr. S. Deadman, who for sixteen years has been head gardener at Gorway, the residence of the late John Whidbourn, Esq., was presented with a very handsome sixteen-day marble timepiece in recognition of his services to the Association. Mr. J. Colman, as the presiding Chairman for the evening, made the presentation, and said that the members felt that they could not allow Mr. Deadman to leave the town without a slight recognition of his kindness and energy on behalf of their Association. He simply expressed the wish of every member that Mr. Deadman would have good health, and be successful in his future career wherever he may reside. The Association have reason to regret the loss of so valuable a member, who had so often given them able and instructive papers on fruit culture. Mr. Deadman briefly thanked the members for their expression of the humble services he had rendered, said whatever value had been set on the papers he had given, that some good would be the outcome of his efforts, whilst wishing the Teignmouth Association every prosperity. Mr. Deadman is a thorough practical gardener, and the Association hope he will soon meet with a suitable situation.

— **LEICESTER CHRYSANTHEMUM SOCIETY.**—The annual general meeting of the members of the Leicester Chrysanthemum Society was held on Thursday, 25th ult. The President, Ald. T. Wright, occupied the chair. Mr. W. Bell, the Hon. Secretary, read the annual report, which showed that during the year there has been a steady increase in the number of members and in the amount subscribed. Last year there were 263 members, subscribing £63 10s. This year there are 267 members, subscribing £67 17s. At the Exhibition held on November 11th and 12th there were 190 entries. A gift of thirty books on fruit culture from Sir James Whitehead, Bart., M.P., was very much appreciated by those members who were fortunate enough to receive one. The balance-sheet showed total receipts amounting to £130 11s. 4½d., expenses amounting to £130 11s. 0½d. A vote of thanks was passed to Mr. W. Bell, the Hon. Sec., on the motion of Ald. Wright, who spoke in high terms of the hard work he had given in the promotion of the Society's interests, and general regret was expressed at his retirement.

— **LIVERPOOL HORTICULTURAL ASSOCIATION.**—On Saturday evening the annual general meeting of the above Association was held in the lecture room of the Museum, William Brown Street. Mr. T. White, the Chairman of the Association, presided, and there was a large attendance of members. Reference was made in the report to the loss the Association had sustained by the death of the late Mr. A. R. Cox, who was a most useful member of the Committee. The report was passed, the financial statement showing a balance in hand of £134 0s. 3d. A vote of thanks was accorded to all past officers for their services during the year. Robert Holt, Esq., Mayor of Liverpool, was appointed Hon. President; W. Fletcher Rogers was re-elected Hon. Treasurer; Mr. G. Blackmore Sub-Treasurer; Mr. Wm. Dickson, 25, Victoria Street, Liverpool, Secretary; and Messrs. Woolley, Playfair, B. Cromwell, J. Madeley, J. Bounds, J. Lowndes, D. H. Johns, T. D. Heany, and Thos. Healey were selected to fill the vacancies on the Committee. A sum of 3 guineas was voted to the Gardeners' Royal Benevolent Institution, and 2 guineas to the Gardeners' Orphan Fund. The spring Show will be held in St. George's Hall on March 14th and 15th, and the summer Show July 26th and 27th. A vote of thanks to the Chairman terminated the proceedings.—R. P. R.

— **HYBRIDISATION AND IMPROVEMENT OF PLANTS.**—Under the auspices of the Scottish Horticultural Association, Dr. J. H. Wilson recently delivered a lecture on the "Hybridisation and Improvement of Plants." After glancing at the early history of the art of hybridisation, reference was made by the lecturer to the great advances of recent times in the improvement of flowers and fruit by its aid. Undeniably there had been much success by haphazard work; it were better, however, to pursue surer and more scientific methods. By a hybrid was ordinarily meant the plant resulting from the fertilisation of the flower of one species by that of another. In a few cases a result essentially comparable had been attained by grafting one species on another, but this method was not reliable. On the other hand, the nature of the hybrid, resulting from the crossing of flowers, could in most cases be approximately anticipated. It, therefore, lay within the power of the operator to attain a certain ideal of form and colour by skilfully blending certain parental characters. The lecturer having fully described a simple flower, and the means whereby seed could be procured, discussed the precautions necessary to the successful fertilisation and hybridisation of well known garden plants. The extremely intimate union of the characters of the parents in hybrid offspring was shown by lantern transparencies of microscopic preparations of new hybrids raised by the lecturer.

— **NORFOLK AND NORWICH HORTICULTURAL SOCIETY.**—The annual meeting of this Society was held at the Guildhall recently under the presidency of the Mayor (Mr. A. R. Chamberlain). The Hon. Secretary read the statement of accounts, from which it appeared that the balance in hand at the beginning of last year was £88 14s. 9d., but owing principally to inclement weather that prevailed at the time of the Rose Show the balance at present is £39 19s. 3d. The reserve fund amounted to £257 6s. 2d. The Chrysanthemum Show, according to the annual report, proved a greater success than ever, and it was extremely gratifying to find that its advance in every respect continued year after year to be so steady. For the first time an expert, Mr. Edwin Molyneux, of Swanmore Park, Bishops Waltham, was retained to judge the Chrysanthemums. His awards gave the utmost satisfaction both to the Committee and to the exhibitors. The report having been adopted, the following officers were elected:—President, Mr. G. F. Buxton; Vice-President, Mr. B. Le Neve Foster, Sennowc

Hall; Treasurer, Mr. S. G. Buxton. Committee: The Mayor, Mr. B. E. Fletcher, Mr. I. B. Coaks, Mr. E. A. Field, Sir Harry Bullard, the Rev. T. H. Marsh, Mr. G. Daniels, and Mr. F. Morris. Mr. J. Green, East Dereham, was elected to fill a vacancy caused by the retirement of Mr. W. Cork. Mr. J. E. T. Pollard was unanimously re-elected Hon. Secretary, with thanks for his invaluable services for the past five years. Messrs. A. W. Preston and W. H. Back were re-elected auditors.

— MEETINGS OF PROTEST AGAINST RAILWAY RATES.—A few of the leading market gardeners of Evesham and district met recently to consider the new railway rates. The following memorial to the Board of Trade was drawn up, and instructions given for the same to be distributed in the district for signatures of those interested in the matter:—"To the President of the Board of Trade. Sir,—We, the undersigned memorialists, being market gardeners and farmers of Evesham and district, desire respectfully to call the attention of the President of the Board of Trade to the grievous injustice inflicted on the market gardening and farming interest by the arbitrary raising of rates by the Midland and Great Western Railway Companies. Competition being now so keen that even the late rates were too high in comparison to the value of the articles, any increase will be simply ruinous to the market gardening and farming interest." The members of the London Wholesale Seed Trade Association also held a meeting on the 20th ult. to protest against the new rates. Amongst other firms represented were Messrs. Hurst & Sons, Watkins & Simpson, Cooper, Taber, & Co., J. Wrench & Sons, and Nutting & Sons. A great meeting was held at the Mansion House on Monday, the Lord Mayor presiding. Sir James Whitehead, M.P., proposed the following resolution, which was carried unanimously:—"That this meeting of traders and agriculturists, from all parts of the United Kingdom, is of opinion that, in view of the persistent efforts made by the railway companies for many years past to secure additional powers of charge, the large and general increase in rates which they have recently made (in spite of their frequent denial of any intention to do so, and immediately after obtaining such powers) has shown conclusively that the fixing of actual rates ought not to be left to their irresponsible discretion."

— R.H.S. CERTIFICATES, 1892.—General Distribution.—The wide area over which the certificates of the Royal Horticultural Society are distributed, for plants and products examined by its Committees, is shown in the following facts. First as to countries, we find that one certificate went to Africa, one to America, one to Belgium, 380 to England and Wales, six to France, three to Ireland, one to Jersey, and two to Scotland. Next referring to the English and Welsh county distribution, we find that two certificates went to Bedfordshire, twenty-one to Berkshire, ten to Buckinghamshire, one to Cambridgeshire, two to Derbyshire, two to Devonshire, one to Dorsetshire, nine to Essex, seventeen to Gloucestershire, five to Hampshire, one to Herefordshire, fifty to Hertfordshire, forty-nine to Kent, ten to Lancashire, two to Leicestershire, two to Lincolnshire, eighty-six to Middlesex, fifteen to Monmouth, two to Norfolk, one to Northamptonshire, eight to Northumberland, six to Nottinghamshire, one to Oxfordshire, one to Shropshire, thirteen to Somersetshire, five to Staffordshire, thirty-eight to Surrey, one to Warwickshire, four to Wiltshire, two to Worcestershire, seven to Yorkshire. As is inevitable, England as a nation takes the lead and naturally exhibits from the home counties, because of the convenience of short distances for travel and transit to the meetings, receive more certificates than the fewer exhibits could possibly do from distant parts of the country, yet Gloucestershire, Monmouthshire, Somersetshire, and Lancashire appear to have done remarkably well. There is this to be said about the honours of the Society, that the merits of the products are *alone* considered, and the Committees would as readily certificate a plant from Kilkenny as from Kew, a fruit from Kentucky as from Kent, or a vegetable from Fiji as from Fulham; so send them along.

LYCASTE BARRINGTONIÆ.

ALTHOUGH one of the oldest members of the genus this *Lycaete* is but seldom met with under cultivation. This is no

doubt due in a great measure to the utter absence of the bright tints common in *L. Skinneri* and the more popular kinds, the flowers being of a uniform greenish-white colour. The freedom with which they are produced, however, compensates for their dull hue, and a well-flowered specimen, especially of the variety *grandiflora*, is by no means an unattractive object. *L. Barringtoniæ* was introduced from Jamaica about 1790, and has been in turn named *Epidendrum*, *Dendrobium*, *Colax*, and *Maxillaria*. A fine plant with fifteen flowers may be now seen in the Orchid houses at Kew.

The variety *grandiflora* was introduced in 1868. It is the largest of the *Lycastes*, having leaves 2 feet or more in length, and flowers as much as 5 inches in diameter. It is figured in the "Botanical Magazine," t. 5706.

#### ONCIDIUM SPLENDIDUM.

The specific name of this *Oncidium* is in no way exaggerated or misleading. Sir J. D. Hooker described the plant in 1871 as "without doubt the finest *Oncidium* hitherto discovered," and even at the present day this description requires no qualification. A native of Mexico and Guatemala, *O. splendidum* was introduced in 1862, but it is only within the past two or three years that it has become at all plentiful. The fleshy deep green leaves are oblong, 6 inches to 1 foot in length, and about 2½ inches broad. The scape is stout and erect, about 2 feet in length, and terminates in a many flowered branching raceme. The flowers are about 2 inches in diameter and very showy. The sepals and petals are yellow blotched and barred with brown; the lip is very large, flat, and entirely yellow. This *Oncidium* should be grown in a basket or on a block; it requires a stove temperature. It is figured in the "Botanical Magazine," t. 5878, as a variety of *O. tigrinum*, and in the accompanying description, by a curious error, the leaves are said to be "2½ feet broad."

#### BULBOPHYLLUM COMOSUM.

Very few of the *Bulbophyllums* are considered worthy of a place in the Orchid collections of the present day, and such as are occasionally met with are cultivated more for some peculiarity in the structure and appearance of the flowers than for their beauty. The species under notice, however, is a graceful and attractive little plant, which may attain a greater measure of popularity than its congeners. It is a recent introduction from Upper Burmah, and was exhibited at the last meeting of the Orchid Committee of the Royal Horticultural Society, when it received a botanical certificate. It is a deciduous species, and blooms before the leaves make their appearance. The creamy-white flowers are individually small, but are thickly crowded on the pendulous racemes, the peduncles of which are erect until the flowers are reached. The sepals and petals are fringed with hairs, which give a light feathery appearance to the racemes. A plant has been in flower for some time in the warm Orchid house at Kew.—A. B.

#### ZYGOCOLAX VEITCHI.

ONE of the most admired of all the Orchids exhibited at the Drill Hall on January 17th was the beautiful bigeneric hybrid represented by fig. 13, page 87. *Zygocolax Veitchi* is the result of a cross between *Colax jugosus* and *Zygopetalum Mackayi* var. *crinitum*, the former being the pollen and the latter the seed parent. It is undoubtedly one of the happiest of the Veitchian hybridiser's efforts in the inter-crossing of Orchids, the blending of the characters of the two plants being effected in a most pleasing and harmonious manner. The form of the flower is accurately portrayed by the engraving; it will suffice, therefore, to describe the colouring. The sepals and petals are pale greenish yellow blotched with chocolate. The short, nearly flat, and very broad lip is pale lilac veined with rosy purple and margined with the same colour. The habit is dwarf, the pseudo-bulbs short and blunt, the leaves, as shown, long and narrow. There is a strong suggestion of the *Zygopetalum* parentage about the hybrid, but it is, as it were, modified and toned down, the contour of the flower being improved by the "Colax blood." In every respect *Zygocolax Veitchi* is a beautiful and charming Orchid, and a distinct triumph of the hybridiser.

#### CYCNOCHES PENTADACTYLON.

The special feature—one might almost write the sensation—of the last meeting of the R.H.S. was a magnificent plant of this species of the Swan Orchid, exhibited by W. W. Mann, Esq., Ravenswood, Bexley (gardener, Mr. Simmonds). On the score of novelty it could not have attracted attention, for the plant is an old one, and has been often seen; but its dimensions and inflorescence were so remarkable that it became the centre of attraction, and was awarded a first-class certificate by the Committee. It had

three very vigorous stems, the largest being nearly a foot long, and about  $3\frac{1}{2}$  inches in circumference. It bore five long racemes of blooms—in fact the plant was almost smothered in wreaths and

of green, and barred with reddish chocolate. The lip is very narrow and clawed, the narrow tubular column curving upwards below it, and expanding towards the tip. The flower is both

FIG. 14.—CYCNOCHES PENIADACTYLON.

flowers, and produced a beautiful effect. Fig. 14 represents one of the racemes. The flower, as will be seen by a reference to the engraving, has narrow sepals and petals, creamy white with tinges

pleasing and peculiar, and in anything approaching the condition of Mr. Mann's remarkable specimen the plant would be undeniably effective.

J. H. TAYLOR.

MESSRS. PITCHER & MANDA send us a bloom of this new American variety, which they consider one of the best for late work. They describe it as a great advance on Miss L. Cartledge. The plant is said to possess a robust constitution, yet is of a dwarf habit, and the flowers last in perfection a long time. This variety, it is stated, was shown last November at the Royal Aquarium, and has been flowering the whole time since. The bloom received is good, and the colouring attractive, the centre florets being creamy white, and the outer ones deep pink.

L. CANNING.

Is there not a mistake in naming this variety Lord Canning? If I mistake not it is the same sort we grow for late flowering, as the description answers so closely to the one under that name, which is an American variety sent to this country during, I think, the spring of 1890. In the autumn of that year I saw a splendid bloom of it in the nursery of Mr. Morton in Darlington, but since that time I have not seen a good flower. I have given up trying to produce large blooms, and now grow the variety for late flowering only, it being one of the best for that purpose. It is pure in colour and of even form, therefore well suited for decoration in a cut state. When cultivated on the large bloom plan it had a peculiarity of going blind in the point of the shoots instead of showing a crown bud in the ordinary way. This, I think, is the general experience of growers. However, by this we have gained a good late-flowering variety, which is, perhaps, of greater importance than for the sake of the exhibition table. We top our plants when 4 inches high, afterwards allow them to grow uninterruptedly, and produce as much bloom as they think fit. Disbudding is not practised.—E. M.

MRS. L. C. MADEIRA.

Is there not a mistake made in classing this variety as a Japanese on page 54? I cannot find it catalogued as belonging to this section. Mr. Owen staged three blooms of it at the Drill Hall in London on January 17th, to which the Floral Committee of the Royal Horticultural Society gave no award. The blooms in question were closely incurved, reminding one very much of Mabel Ward in the form of their florets, but which are narrow and pointed, and the manner of incurving. The colour is a rich orange yellow. It promises to be a good late flowering variety. It appears to have been highly thought of in America, judging from the honours it has received in that country.—E. M.

JOHN LAMBERT.

LIKE a "Yorkshire Bit," I have watched this wordy duel, and have no desire to say one word either for Mr. Molyneux or Mr. Lambert; both are equally qualified to hold their own, but in all fairness to the variety John Lambert I should like to state my opinion, and that is I consider it far superior in form and much more reliable than the old Golden Queen or Emily Dale. After I grew John Lambert side by side with those varieties I was so well pleased with the new comer that I at once threw the older stock away. So far as I can judge, Mr. Lambert only claims for his namesake that it is an improved form; in that I readily support him, for it is "form" we require, the same as in John Doughty being an improved form of that flat reflexing variety Bronze Queen; but Chrysanthemum growers, as a body, well know which varieties are best after a three-years test.—J. D.

#### INCREASED SIZE OF SHOW STANDS.

THE letters of "Sadoc" (page 55) and "D." (page 76) again raise the question of an authoritative increase of the size of the stands for the exhibition of Japanese blooms. As I am one of those who differ from "Sadoc's" estimate of conferences, and am rather inclined to the belief that the conclusions arrived at by a large body of experts are not likely to be of less value than the expressions of opinion of a single individual, I think it scarcely necessary to again traverse the ground covered by the late conference on show boards; suffice it that, practically, all the points mooted by "Sadoc" were raised and considered at the conference, and by an overwhelming majority decided in a sense adverse to the views of your correspondent.

"D." tells us that "it has already been so conclusively shown that there is no need whatever for the increase in size of the stands that it is almost certain in a year or two we shall hear no more about it." It would indeed be interesting to learn when and where it has been so "conclusively shown." A sweeping and confident assertion will scarcely adequately supply the place of proof. Although a very steady reader of the horticultural papers I have seen no signs of the conclusion so dogmatically alleged.

So far as I am aware the matter stands thus. Of the thirty-seven representative exhibitors consulted by Mr. R. Falconer Jameson, thirty-five appear to have assented to the principle of the necessity for an increase. At the N.C.S.'s conference thirty-eight voted for and only seven against the resolution to adopt, compulsorily, the new standard

size proposed by Mr. Drover—namely, with 7-inch intervals between the holes (centre to centre), and I understand that the opposition of some of the dissentients was directed rather against the principle of compulsion than against the desirability of an increase.

Mr. H. Brown, in his very able letter, page 76, tells us that in his experience "90 per cent. of growers are in favour of reform." If I may substitute "leading exhibitors," whom the question practically alone concerns, for "growers," I can add my testimony to the like effect. There are of necessity a large body of growers who never, or rarely, enter the charmed circle of prizewinners, to whom the retention of a system which enables smaller blooms to be displayed to better relative advantage would doubtless be very welcome, and there is the "smart" exhibitor referred to by Mr. Brown; and I would ask is Mr. Brown's letter exactly indicative of that speedy burying of the question which "D." manages to persuade himself lies in the near future?

Upon one point, however, I find myself able to agree with both "Sadoc" and "D." The former tells us that "it will never do to allow all (exhibitors) to employ whatever size they thought fit," and "D." adds that "if exhibitors are allowed to have boxes for Japanese flowers up to any size they like there will be chaos." Exactly, and I would add that nothing can be more undesirable, or calculated to confuse and mislead the Judges than to have, as was the case in a leading Japanese class at the late November Show of the N.C.S., certain of the competitors using the new conference stand, others the old standard size, while another exhibitor had a stand with the intervals midway between the two—namely, 6½ inches.

So long as the law of "comparison under unequal conditions" remains—and Nature's laws have a way of holding their own, even in face the most sweeping assurances to the contrary—so long will such a condition as I have described militate very greatly against the formation of an accurate judgment upon the several exhibits. I think that during the present transitional period, and until a larger standard size shall, either by authority or by growing usage, become universal, the exhibitor should have the alternative only of the present 6-inch size or that of the "Conference" stand. All other sizes should be prohibited.

I wish that I could agree with "D." that a limitation of the size of the board could restrain the rage for more bigness, but with the practical evidence of the audit of last season's shows before us, it is impossible to assent to the conclusions of your correspondent.

It is true that "style" and "refinement" have recently received in some quarters more pointed recognition, but when we have before us the fact that very many of last season's novelties give to us all that can be desired in these directions, and yet have the added quality of giant size, the last argument against the adoption of a show stand large enough to permit of a proper and critical judgment of the exhibit must disappear.—S.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

##### THREE-DAYS EXHIBITIONS.

I WAS fully in accord with the N.C.S. in holding a three or four-day Exhibition to celebrate the centenary of the Chrysanthemum; but what exhibitor ever expected a continuation of a three-days Exhibition? They rightly choose the best dates in November for a Show, but exhibitors from a distance are (if they show at the N.C.S.) practically debarred from exhibiting elsewhere, as the preparation for going to the N.C.S. and the return journey take up the best part of the week. Perhaps the three-days Show is to suit the Aquarium Company; if so, and exhibitors dislike it, they have the remedy—"don't go." Then how about the increase of membership? Members will not continue unless they are partly considered, and I am not aware that a single member has been asked his sanction to such a waste of time alteration. The Crystal Palace Company have an excellent Show (only two days), and exhibitors from a distance are able to leave in sufficient time to reach their destination the same evening. The N.C.S. Committee are elected to carry out the work of the Society, and no one grudges them their onerous duties; neither do I wish to be dictatorial, but I, with many others, look for consideration. Shall we get it when the schedule comes out? and will its issue be deferred till the Committee have settled the Beauty of Exmouth case?—J. DOUGHTY.

##### THE BEAUTY OF EXMOUTH CASE STILL UNSETTLED.

ALLOW me to thank Mr. Harman Payne for answering my query, or at least as far as he was able to do so; but I am sure the majority of readers will consider the answer a most unsatisfactory one. It amounts to this. The General Committee acted in a straightforward manner, and, on the spur of the moment, the sub-Committee thought it best to act with greater caution, and consulted a lawyer. The Committees and both cases are in connection with one Society, and there is also another similarity in both cases. The difference in the cases is this, Mr. Wells repeatedly requested the Secretary to lay his complaint before the Committee, but he (the Secretary) declined to do so. Mr. Wells took other measures, and brought the matter before the General Committee in such a manner that the affair could not be smothered, and the result is such that says little for the wisdom of the Chairman and Secretary.

In the Beauty of Exmouth case a sub-Committee was appointed who wished the public to believe they could not investigate the affair until the name of the member complained of was before them. Then, so it states, a lawyer was consulted as to whether it would be libellous to "investigate" the charge any farther, and he advises the sub-Committee to cease further action. I do not wonder at Mr. Harman Payne

disclaiming credit for giving such advice (perhaps all did not know Mr. H. P. is a lawyer). Will Mr. Harman Payne say how the sub-Committee received the advice? Are they lamenting in sackcloth and ashes the block to further investigation?

I have consulted a lawyer, and he informs me that it is ridiculous to assert that any society cannot freely investigate a charge of irregularity on the part of its members, especially when such charge is likely to injure the character of the Society. He says there is nothing libellous in it, and the Society runs no risk whatsoever.

Mr. Harman Payne says there is a vast difference between Mr. Wells' case and mine. Mr. Wells had documentary evidence to prove his; then why, may I ask, did not the sub-Committee give me an opportunity to produce what evidence I was able to in support of the charge?

Can anyone tell us who suggested the appointment of a sub-Committee? My own opinion is that had the General Committee investigated the affair we should have heard nothing about consulting a lawyer. Mr. Dean in a letter informed me that it was very likely I should be called upon to substantiate the charge. As yet I have heard nothing more about it. I really think, if the offending member must be shielded, it should not be at the expense of the innocent members of the Floral Committee, for it is quite likely that some of the trade growers are being accused wrongfully. Was this why Mr. Cannell wrote?—W. J. GODFREY, F.R.H.S., *The Nurseries, Exmouth*.

THAT my name has appeared in your papers in connection with this case, and being a member of the N.C.S. Floral Committee, will be sufficient apology for my writing a few lines upon this subject. I do so if possible in the hope of clearing up some of the errors into which several of your correspondents have fallen. The length of time that this matter has been under discussion, coupled with the many side issues which have been introduced, has no doubt been the cause of the very hazy ideas many of your readers and correspondents must have of the real facts. With the side issues I have nothing to do, and will confine myself to the complaints of Mr. Godfrey and Mr. Wells; and I will first deal with the complaint of the former as being to my mind the more serious of the two, although that of the latter was brought to the notice of the Secretary some three weeks before the Godfrey incident occurred.

On the 20th October, 1892, you published a short notice that you had just received a complaint against a member of the N.C.S. Floral Committee, and at a meeting of the General Committee on the 24th October, which had been previously convened, our attention was called to this paragraph, and at the suggestion of the Chairman, the five officers were appointed as a sub-Committee to inquire into the subject. Mr. Godfrey's letter of complaint was at that time in the possession of the Chairman, but I, as well as the other members of the General Committee present, was quite in ignorance as to the meaning of the notice, except that it was a complaint against a member of the Floral Committee, to which I have the honour to belong; and we accepted his suggestion that these officers should inquire into the matter, feeling that they would do what was necessary to protect the good name of the Society and denounce the member if he had really acted discreditably.

The appointment of this sub-Committee was made on the 24th October, and although the matter was of considerable importance and required prompt attention, they did not present their report until eight weeks had elapsed, having held three meetings in the meantime.

Their report (save the mark!) simply recommended that no further action be taken in the matter.

Now, to my mind, this was most unsatisfactory, and as I have given much of my time to the Society on Committees, sub-Committees, &c., I consider I have a right to look to the officers to protect me and other members of the Floral Committee when accusations of this description are hurled at that body; and for this reason I took upon myself at the meeting on the 19th December to go into the matter at great length in order to point out to the General Committee my disapproval of the conduct of the sub-Committee, and gave reasons why I should vote against the adoption of that report. Several of the Committee spoke agreeing with my remarks; many of them were of my opinion, but few indeed have the courage of their convictions, and it is a curious fact that not one of the remaining fourteen of my fellow Floral Committee-men uttered a remark either in favour of or against my comments.

There is one thing this sub-Committee entirely lost sight of, and that was the wording of the resolution of the General Committee appointing them to "inquire into the subject." Had this resolution read to "inquire into the subject and report to General Committee the best way they could shuffle out of it" we could have understood their report.

Then, again, much nonsense has been both written and talked about publishing the name of the offender, and I do not hesitate to say that there never has been any necessity for publishing his name. Mr. Godfrey's letter, published in your paper, sets out without a doubt that he is a trade grower, and surely none of us are hard-hearted enough to wish to injure a man in his business, whatever his shortcomings may be. A report from the sub-Committee, either condemning the acts of the member complained of, or setting out that after investigation the Committee had found the charges were unfounded, is the kind of report which would have done more credit to five business men such as formed this sub-Committee. But as the matter now stands, a serious charge has been made against a body of men of having one among them who, in his capacity as a member of the N.C.S. Floral Committee, acts dishonourably, and this charge remains unanswered.

Finding the cry of "publish his name" does not have the desired effect of putting an end to the heckling the N.C.S. receive at the hands

of your correspondents, they then proceed to raise the libel ghost as their excuse for allowing the members of their Floral Committee to be dragged through the mud consequent upon the act of one of its members. This cry I have no hesitation in saying had great weight with the majority of the General Committee, and helped the sub-Committee in carrying a resolution adopting their report; and I would remind the sub-Committee if they are so ignorant of the law of libel, that an opinion expressed honestly, fairly, and without malice, is not libellous. Libel may be defined as a tortuous act consisting in the malicious defamation of another made public by writing, printing, pictures, or effigy, in such a manner to expose him to public hatred, contempt, ridicule, reproach, or ignomy. Any fool can institute an action for libel, but to entitle a person to succeed he must prove the publication was not made honestly, fairly, and without malice.

The Wells incident also requires a little explanation to make it clear to many of your readers. About the 1st October Mr. Wells received from a member of the N.C.S. Floral Committee a letter, in which the following words occur:—"I have been expecting to hear from you in respect to my account, which I trust will be paid before long . . . . I shall certainly take steps to prevent you showing among us at the National Chrysanthemum Society if the account is not paid." This letter was placed before the officers of the N.C.S. by Mr. Wells, but notwithstanding the fact that this was a direct abuse of the trust placed in this person when elected a member of the Floral Committee, the officers declined to interfere, and the complaint was not brought before the Society. Upon this Mr. Wells sent round to the members of the N.C.S. a circular to air his grievance, as he could obtain no other redress. One of these circulars reached me, whereupon I obtained a copy of the correspondence, and brought the matter before the General Committee at their meeting on the 19th December last.

Mr. Harman Payne is quite correct in his statement that the two cases came before two separate Committees, but this requires some little explanation. Mr. Godfrey's complaint reached the General Committee on the 24th October, whereupon they appointed a sub-Committee; but Mr. Wells' complaint was never mentioned to the General Committee, although it had been known to the officers since the first week in October. Therefore the General Committee on the 24th October having had one exhibition of the careful way a sub-Committee of officers watched over the good name of the Society, took upon themselves to express an opinion in this case, and on a motion made by myself, a resolution condemning the acts of the member complained of was carried. If anyone is to blame for not naming the individual I accept that responsibility myself, for as I before said, there is no necessity to name him; he no doubt reads the gardening papers, and I venture to think he will not again abuse the position he occupies.

I have given notice that at the annual general meeting to be held on the 20th February I will move the adoption of a new rule, by which any member guilty of irregular conduct may be expelled, and I trust that every member of the Society who can will attend at Anderton's Hotel on the occasion and support this motion.—GEO. S. ADDISON.

[We also know on high legal authority that the publication of the name of the person mentioned in Mr. Godfrey's letter in the first instance was not in the least necessary for the purposes of official investigation. We could have published the letter, but had no wish to do so; and with the object of having the matter settled amicably by the officials this letter was, with Mr. Godfrey's ready consent, placed in the hands of the Treasurer. We had in view a complete investigation, and this we thought would be welcome to all persons concerned.]

We were bound to intimate our possession of this letter, in which the action of two persons was objected to, because both the Secretary and the Treasurer of the N.C.S. had written (the former on October 3rd, and the latter on October 8th) declining an investigation as requested by Mr. Wells into the conduct of a member of the Floral Committee—conduct which when it was known to the General Committee was denounced.

No public journalists worthy of the name could permit themselves to share the responsibility of preventing an inquiry into an alleged grievance of a serious nature stated in specific terms; and as we were aware of a strong undercurrent of disquietude we thought the time and opportunity had arrived for an examination into the allegations on their merits without anything approaching the publicity the case has assumed, and which might have been so easily prevented.

Whether Mr. Godfrey was right or wrong in his allegations was and is a matter of indifference to us; but we are of opinion that if he was wrong, the Committee should have found that out by examination. As the discussion has proceeded no one can have failed to observe the strong desire of Mr. Godfrey for searching inquiry, and he has frankly offered to waive all legal rights he may have, as suggested by Mr. Fowler, conditionally that every person implicated would do the same. Why was not this strictly fair and reasonable proposition accepted? The whole disturbing question might have been settled long ago on that basis.

It is to be presumed that no members will object to Mr. Addison's new rule who do not fear expulsion for irregularity, and it may, therefore, be expected to be unanimously adopted.]

#### MR. GODFREY'S CHALLENGE.

AFTER reading Mr. Godfrey's manly and straightforward letter in your issue of the 19th inst. (page 54), I quite expected this week to find that the challenge had been accepted; but instead a long letter from

Mr. Harman Payne, trying to explain the difference between "tweedledum and tweedledee."

Your correspondent also takes Mr. Godfrey to task for saying a few weeks since he would leave no stone unturned to clear himself—that is, if necessary, to take legal proceedings; but Mr. Godfrey frankly waived his right to accept the most fair proposition of Mr. Fowler.

No long letters, no legal quibbling can do away with the fact that Mr. Godfrey's challenge has not been accepted, and the readers of your paper must and will judge for themselves who is in the strongest position.

I am afraid after the Wells exposure and Mr. Godfrey's Beauty of Exmouth case that many members of the N.C.S. will lose confidence in the impartiality of the officials, who have no right to favour one member of the Society more than another.—A GROWER.

[We add, a good grower too, and the hearer of a well-known name in the Chrysanthemum world.]

## CANKER—PROPOSED EXPERIMENTS.

(Continued from page 69.)

As indicated last week, I now propose a few experiments that may be usefully made by Mr. Kruse or others who may be able to carry them out.

Take six Hawthornden Apple trees on English Paradise stocks, clean, healthy, with a few blossom buds, and a convenient size for potting—say, three years from the bud; also take three trees infected with canker.

Experiment I.—Pot three of the healthy trees, the roots free from earth, in drift sand, draining the pots well, and making the sand firm. Preserve all the roots possible. Stand each pot on two bricks, placed a little distance apart, and so that the aperture of the pot is free, then surround the pots with ashes, bringing them up level with their rims, the site being open, but sheltered from winds. Label the trees 1, 2, 3. Prepare a nutrient solution as follows:—Nitrate of calcium, sulphate of ammonia, and nitrate of potash 1 oz. each, water 30 gallons, mix. Water all the trees with rain water until the buds commence swelling, then keep the sand regularly moistened with the nutrient solution, and when the leaves are fairly developed they may be found pale and yellowish. Add 1 oz. of sulphate of iron to the preceding solution, and water No. 1 and 2 trees therewith for a fortnight, when, the leaves being still pale and yellowish—an indication that there has not been any increase of the chlorophyll—add 4 ozs. of disodium phosphate to the solution last named, taking proper proportions of the elements and water in all the formulas, and water No. 1 tree with it. In a week's time the leaves of this tree will have acquired a deep green colour, proof that iron alone is not sufficient to increase the chlorophyll, nor energise the protoplasm, so as to cause cell division, for until the phosphorus is introduced the sulphur of the iron sulphate is practically inert.

No. 2 tree—still watered with the ammoniac, calcic, ferric, and potassic solution—remain pale and yellowish in its leaves and young growths, also fruit (if any). No. 3 tree, so far, has been nourished by the ammoniac, calcic, and potassic solution, and its foliage is quite as good in size and colour as No. 2, yet pale and yellowish; add, therefore, 4 ozs. of disodium phosphate to the first-named solution (nitrate of calcium, sulphate of ammonia, and nitrate of potash), and water No. 3 tree with it. What then? In the course of a few days the growths (young) enlarge, cell division has taken place, the sulphur of the ammonium sulphate has combined with the phosphorus and energised the protoplasm, but there is not any pronounced increase of the chlorophyll. The trees may be treated according to the last régime given for each through the season and the difference in their growth, the perfection of their fruits (if any), the formation of buds, and the ripening of the wood will afford useful lessons. Only one tree will be satisfactory, that which has received a due supply of nitrogenous and mineral food—namely, No. 2. The foregoing experiments have been suggested by the researches of Hoppe-Seyler in 1879, and those of Herr C. Loew in 1892. They are practical deductions from the teaching of science, which it is high time the horticulturist should avail himself of, and Mr. Kruse seems earnest in the matter. He does not, however, state what cultivation his ground received before planting with fruit trees. Was it subsoil ploughed or trenched? If not, there is probably a plough pan—that is, a layer of aluminous and ferrous particles more or less cemented together by the lime dissolved and washed into the soil immediately below that cultivated by the plough. This is important for our purpose—the potting of the other three healthy trees; but I will presume that the soil has not had any special preparation mechanically for the fruit trees.

Experiment II.—Pot one of the healthy trees in the top 9 inches of soil, taken out squarely, label it No. 4; another in the top 15 inches, No. 5; the other in the top 21 inches, No. 6. Place the potted trees in a similar position to that described for those in Experiment I, and surround with ashes. Supply rain water to all as required until the buds commence swelling, for, from that time forward until the fruit is fully swelled, they require nourishment, and we propose to treat each tree differently, as follows:—No. 4, Water with the drainings of farmyard manure diluted to the colour of mild ale, paler rather than darker, at every alternate watering through the season. That is a complete manure for present needs. If that cannot be had, take the drainings of stables or cow houses, or both, urine chiefly composing the contents, and add a peck of fresh horse or cow manure to 20 gallons, mix, stir twice a

day, morning and evening, for two days, then add 100 gallons of water, straining before use through a coarse sack. If the last named substances cannot be had, dissolve 1 lb. of Peruvian guano in 20 gallons of water, and supply it to the tree. If the foliage, by the use of the nutrient solution just mentioned is not of a healthy green colour, but pale and sickly, iron and sulphur is wanted. We have them in soot, sulphate of ammonia, 3.58 per cent., and in sulphate of lime, 11.05 per cent., for sulphur, oxides of iron and alumina, 15.69 per cent., for iron; therefore form dry light soot into a thick paste with water, and use a tablespoonful to each gallon of water at every other watering, and occasionally after the leaves become, as they will, a deep green colour. That No. 4 tree will be healthy and fruitful in the current year and the next because well nourished, and we have proved that, if the tree carry deep green foliage by the use of stable or farmyard manure in liquid form, the soil contains enough iron and sulphur, and that farmyard manure is a proper application for such land without supplementary supplies of sulphur and iron, or they need only be supplied to augment the crops. We have also seen that sulphates of ammonia and lime and a supply of iron is beneficial where the foliage assumes a pale hue and does not form sufficient chlorophyll for health and profitable production.

No. 5 tree may be nourished by alternate waterings of rain water and sulphate of ammonia 1 oz. to 4 gallons of water, as the soil is well provided with potash, phosphoric acid and other elements, but I hardly anticipate this after midsummer, not on account of the lime, 3.91 per cent. being excessive, but because it is too little to form nitrate of calcium fast enough; therefore a supply of phosphatic and nitrogenic elements may be necessary, as they are, if the sulphate of ammonia is not sufficient. But it has served our purpose, if No. 5 tree does not flourish with the sulphate of ammonia it is not a proper dressing for Mr. Kruse's soil unless the iron is sealed in a pan, and it would be better to break it up and apply farmyard manure than waste money on sulphate of ammonia, for the iron would only seize and hold it fast, unless liberated by roots.

No. 6 tree, supplied with nitrate of potash, 1 oz. to 4 gallons of water and 2 ozs. of bone superphosphate to 4 gallons of water, mixed = 8 gallons, at every alternate watering, that is, rain-water once, then the mixture, followed by the rain water, and so on, ought to produce healthy, deep green foliage, and sturdy growth; if not the first, and the latter is stunted, supply nitrate of soda, 1 oz. to 4 gallons of water, with 1 dr. of sulphate of iron added to the nitrate solution, once a week instead of one of the other nutrient waterings. Healthy vigour must follow, and this mixture of manure is likely to meet Mr. Kruse's requirements.

Experiment III.—Two of the trees selected for this crucial test must have one or more abnormal swellings each, otherwise they are not cankered by *Nectria ditissima*, and no swelling or excrescence caused by American blight or woolly aphid must be mistaken for canker, though the latter likes a canker-infested wound, and is often associated with the fungus, which, by striving to enlarge the wound, causes the tree to push an abnormal amount of cellular matter to cover the wood, and that being tender the aphid can the easier abstract the tree's juices, so that both evils flourish together. If the trees have any aphid in the cankered wounds, dress them with methylated spirit; then cut out the whole seat of the canker in one tree, as described in a former communication, wash it with a 6 per cent. solution of sulphate of iron or carbo-holic acid, diluted with a dozen times its weight of water. Treat every cankered spot on that tree similarly, pot it, and label it No. 7. Pot the other tree just as it is—cankered, swelled abnormally around the wound or wounds, ticket it No. 8.

The other tree has some wounds not marked by abnormal excrescences, the new bark around the wounds being only slightly raised, pot it and attach a label No. 9. Afford these trees similar conditions to the other six trees.

No. 7 tree must have its wounds dressed when dry with some styptic to keep out the weather. Avoid all tars; shellac dissolved in alcohol is a capital dressing for all wounds or cuts on trees. Apply a plaster of cow manure and clay over every wound, reaching well over the bark, and renew as necessary throughout the summer. Also apply a little of the following mixture every fortnight from the time the buds move until October—5 ozs. bone superphosphate, 3 ozs. nitrate of potash, 1 oz. sulphate of lime, mix, and do not supply more than  $\frac{1}{2}$  oz. to a 12-inch pot. Afford an all-round manure as described for No. 4 tree at every alternate watering, except when the afore and after-mentioned top-dressings are applied, at which water only at that and the succeeding two waterings must be supplied. When the first leaves are fairly developed top-dressings may be given every other week, but not that in which the other is supplied, up to mid-July of Thomas' phosphate powder 10 ozs., nitrate of soda 5 ozs., and  $\frac{1}{2}$  oz. sulphate of iron, mix; dose,  $\frac{1}{2}$  oz. per 12-inch pot. Treat No. 8 and 9 precisely the same as No. 7. What are the results? No. 7 has put out a fine healthy callus, and covered over a large extent of the wound surface with beautiful new bark, and its growths are sturdy and full of promise. No. 8's excrescences have enlarged enormously; the tree has thrown out cellular substance all round the wound or wounds, and perhaps succeeded in entirely closing the gap and covered the wood with fresh bark. The tree has won. It may for a time hold its own, an unsightly swollen limb is the consequence, and outside that sooner or later the fungus will push its mycelium into the inner bark outside the swollen part of the limb and the smooth bark becomes discoloured, dead, and it cracks and peels off—the "fruits" of the fungus have been perfected, and are scattered by the winds. But the tree does not always cover over the cankered wound, especially in those of Ribston Pippin and

King of the Pippins, the callus being strongest and making most effort on the upper side of the wound, which does nothing but favour the fungus, the tree making spasmodic growths, a long strong shoot here and there; larger in leaf and better in colour than those of a tree free from cankerous attacks, whilst the other parts of the tree exhibit extreme weakness, and it is an unprofitable tree, as well as an eyesore.

No. 9 shows good progress in covering the wounds with new bark, yet slower than in the case of No. 7, from whence the canker had been incised and a healing plaster applied. There is, however, no abnormal swelling around the circumference of the wound, and, unless canker fungus spores enter that wound and it does not become a repository for wet and the wood decay, it will heal over in time, shorter or longer according to its size and the vigour of the tree, and bear fruit profitably indefinitely.

The trees must be kept clean by syringing occasionally, and an insecticide be promptly applied if insects appear on the foliage and young growths, for it is quite as necessary to keep parasites in subjection as to apply manures to the soil. Top-dressings of rich compost, partially decayed manure, and turfy loam must not be used in the experiments, for, however, essential to the cultivation of fruit trees in pots, the top-dressings would frustrate our ascertaining the capabilities of the soil, because the top-dressings are extraneous and contain more aliment than the soil itself: or 1, food in full measure and in assimilated form, therefore available for immediate absorption and nutrition; 2, increase the rooting area and so provide a number of rootlets in the best condition for absorbing nourishment; 3, the roots so encouraged enable the cultivator to supply double the amount of food to the trees it were possible to do were they restricted to the soil in which they were potted. Experiments, like medicine is taken, must be carried out in strict accordance with the instructions, and the régime prescribed be strictly adhered to, if the issue is to show well defined lines of safe guidance in practice. —G. ABBEY.

(To be continued.)

### WALDSTEINIA TRIFOLIA.

ALTHOUGH introduced into this country many years ago *Waldsteinia trifolia* (fig. 15) is not so widely known as it should be. For planting in all sorts of positions, either in exposed places on the rockery, or in the deep shade of woods, it will be found very useful, as it grows in both equally well.

It is also a very desirable plant for a place near the front of a mixed flower border. It is dwarf in habit, seldom attaining more than a foot in height. The loose corymbs of Buttercup-cup-like flowers are very attractive, and are developed profusely. The leaves, which are divided into three leaflets, are borne on creeping chiefly underground stems; they are slightly airy and serrated at the margins.

### NURSERY NOTES.

MESSRS. E. D. SHUTTLEWORTH & Co. (LD.).

PECKHAM RYE is near enough to London for a call to be made at Messrs. Shuttleworth's nursery there without a great sacrifice of time on the part of a busy man. The establishment is about half a mile from Honor Oak Station, on the L.C.D.Ry. The Company is a young one, and if the evidence of one's eyes is to be believed it is going ahead very fast. In addition to a number of existing houses, three structures, 100 feet by 36, are in course of erection, together with a range of pits and frames on original designs prepared by the active Chairman and Managing Director, Mr. Charles Hicks. The fact that the new houses are being erected by Messrs. Winch & Co. is sufficient evidence of their quality. With the increased facilities at command the Company will have improved chances of coping with its rapidly growing trade.

Visitors to the International Horticultural Exhibition last year (where Messrs. Shuttleworth & Co. secured the highest honour which it was in the power of the Committee to award) and to the Drill Hall on various occasions can hardly have failed to remark the admirable condition in which the firm's plants are invariably exhibited. Many fine specimens were amongst them, but, large or small, they were all excellently grown. The same condition of things is observable in the Peckham Rye nursery. Health and cleanliness prevail throughout, and the ruling principles in force are such as demand respect. "Nothing is too small for attention, nothing too much trouble," forms one of the leading mottoes, if such it can be termed; and courteous attention, without importunity to purchase, is another point on which great stress is laid.

Palms and Cycads are very extensively grown. Such leading market kinds as *Latania borbonica*, *Areca lutescens*, *A. Baueri*, *Phoenix rupicola*, *P. flexuosa*, *P. tenuis*, *Cocos Weddelliana*, *Kentia Belmoreana*, *K. Forsteriana*, *K. Canterburyana*, *Corypha australis*, and *Geonoma gracilis* are cultivated in large numbers, and there are some very fine specimens of both the *Latania* and *Kentia Forsteriana* observable. *Cycas revoluta* is cultivated on a scale rarely seen. There are two large houses full of plants, all of goodly proportions and glistening with health. *Crotons* and *Dracenas* form another leading feature. There are some fine plants of *D. lineata* in tubs and a splendid stock of *D. Lindenii*, the plants

being numerous and finely coloured. *D. Goldieana* and others are also well represented. Amongst the *Crotons*, which are in beautiful condition, there are large stocks of *Reidi*, *Morti*, *Queen Victoria*, *Exquisite*, *Laingi*, and *gracillimum*. Messrs. Shuttleworth & Co. grow these plants extremely well, and in consideration of the fact that their popularity is increasing again, the policy is a wise one.

*Asparagus plumosus nanus* forms another "leading line" at Peckham Rye, there being abundance of clean and healthy young plants awaiting the orders that will come in due course. *Araucaria excelsa* and *A. glauca* are also in strong evidence, the former in particular. The stock is large and the plants in the best possible condition. *Aralia Sieboldi* and its variegated form are extensively cultivated, and nothing but praise can be found for the condition of the plants. *Aspidistra lurida variegata* is another plant in constant demand, and it is to be seen in the same

FIG. 15.—WALDSTEINIA TRIFOLIA.

condition as the others. Specially noteworthy are some stately plants of *Aralia Chabrieri*, with its dark glossy leafage and stems. It is particularly effective in a group of plants, and was prominent in Messrs. Shuttleworth's group at the Crystal Palace Chrysanthemum Show. Ferns have special attention, and the leading kinds are present in large numbers and good quality.

Amongst flowering plants are observable large numbers of *Azalea indica* and *mollis*. The latter is forced very extensively, and early batches are now coming into bloom. Lilies of the Valley are also forced on an enormous scale. Double Primulas for cutting and Carnations for stock, including the valuable Winter Cheer, hold prominent places. A number of plants of *Boronia megastigma* shed delicious fragrance in a large house. If Messrs. Shuttleworth's stock of it were distributed over as many amateurs' greenhouses what a delightful feature would be added to them. *Sonerila orientalis variegata* is not in full bloom, but its foliage is attractive, and a few stray blossoms bespeak its beauty when in flower. A very large number of *Gardenia intermedia* is grown, and the plants, which are pictures of health and cleanliness, are just plumping up their flower buds. Pot Roses, though not in bloom, are largely and well represented, while the same remark applies to *Eucharises*. Of Orchids large and healthy stocks of *Cattleyas*, *Cypripediums*, *Odontoglossums*, and other popular kinds are discoverable, numbers of spikes showing in a cool house.

Roses, fruit trees, shrubs, and hardy plants are not grown at the Peckham Rye Nursery but at Fleet in Hampshire, where another large establishment belonging to the firm exists. Of these the *Journal* representative can only speak from the specimens he has seen at the various shows. These, however, are sufficient to convince him that when the time for a journey from Fleet Street to Fleet arrives he will find there the same excellent practice as prevails in the London stronghold.

## EXHIBITING CARNATIONS AND OTHER FLOWERS.

LAST August at the great Horticultural Exhibition at Shrewsbury an exhibitor from Birmingham staged (not for competition) a fine display of 500 cut blooms of Carnations and Picotees with long stalks neatly arranged in small bottles, thus showing the character of the flowers as growing in pots or borders. This idea has evidently "caught on," for in the new schedule of the Shropshire Society a class has been made for a collection of Carnation and Picotee blooms shown with their own foliage and buds, not dressed in any way, and without ties or bands around the calyx or paper collars. The prizes offered are £5, £4, and £3, a silver medal of the Society to accompany the first prize, and a space of 9 feet by 6 feet is allowed for each collection. The date of the Exhibition, August 23rd and 24th, is too late for the southern growers, also late for those about Birmingham and south and west of it; but the more northern growers, especially those in Scotland, should be well in just then, and it is to be hoped that a fine display and a good competition will result. In such a class border varieties can be freely used; these are now being cultivated largely, and the display made last year to which I have alluded was very much admired. Plants in pots are not admissible, as the class is in the cut bloom division of the schedule.

It is well known that the Shrewsbury Show is always a remarkably fine one, and for two or three years past a strong one for cut flowers. This part of the annual Exhibition increased wonderfully last year, and will be still more developed this with such generous prizes. The Committee, with the two excellent Secretaries, Messrs. Adnitt and Naunton, are always ready to grasp any new ideas, and collections of various kinds of cut flowers now form an important feature. Liberal prizes, as in the class for Carnations, are offered for a collection of cut Roses, space 12 feet by 6 feet, for nurserymen only, and this gives an excellent opportunity for a display of all classes of Roses then in bloom; but the date is rather late for many of the summer blooming kinds. Still, there will be sure to be a good display, and an open field for taste in arrangement.

Collections of Dahlias, with a space of 15 feet by 6 feet for each, having just the same prizes offered, and the initial display of last August will, no doubt, lead to a much extended competition this year. Collections of Gladioli, Begonia blooms, have generous prizes offered for them, and there is an excellent class for a collection of hardy border flowers (annuals and shrubs excluded) to fill a space 15 feet by 6 feet, for nurserymen only.

I venture to say that the adoption of these collections will become very popular, for with my experience of a large exhibition in August last, when liberal prizes were offered for collections of Dahlias, we had seven splendid exhibits, each occupying a space of from 15 feet to 22 feet in length by 3 feet 6 inches wide, and much taste was displayed in arrangement. I may also add that at a great Rose show we purpose holding in Birmingham in July next, prizes will be offered for a collection of Rose blooms in a given space, in the hope of seeing included many old-fashioned garden Roses, climbers, Gallicas, Hybrid Chinas, and others seldom seen now.

The "collection" style of showing is also to be seen in great force at Shrewsbury with vegetables. It is always a wonderful display.—W. D.

## HARDY FRUIT GARDEN.

**Pruning and Nailing Wall Trees.**—Let this work be forwarded and completed before the stress in other departments of the garden commences. Another cogent reason for its early furtherance is the uncertainty of the weather. When mild and dry considerable progress can be made. Boards should be laid upon soil that is loose, damp, or liable to be pasty when trod upon. This facilitates the progress of the work. Trees that have had the proper amount of attention during preceding seasons will soon be disposed of. Old straggling neglected specimens can only have a start made in the attempt to renovate them, as they require patience, and more than one season's manipulation to bring them into form and fruitfulness. Some will need the expenditure of too much time and labour in order to renovate them without the promise of sufficient good resulting. These will be better cut back for grafting or grubbed up entirely, their place being taken with young trees of the same or better varieties, renewing or improving the soil, however, before doing so.

**Pears.**—With all forms of trees examine the main branches first to see that they are not too thickly placed. Those of horizontally trained trees on walls, or espaliers in the open, ought not to have branches closer together than 9 inches. The large branches of aged trees, as well as strong-growing varieties, are better placed for good cultural requirements when not nearer together than a foot.

**Spurs.**—The removal of crowded spurs, together with the shortening back of elongated clusters which project too far from the wall is more or less required every season. It is advantageous to have the fruiting

spurs as close to the wall as possible, in order that the blossoms and young fruit may have the aid of its protective influence. There are no benefits derived from long spurs.

**Position of Fruit Buds.**—In large projecting spurs the most fruitful buds are found at the extremities, while those lower down nearer the main branches are of no use whatever, from the fact that they constantly exist in a partially shaded position away from the developing influences of light and air. Well-placed back buds if allowed free access to better influences during the growing season would soon gather plumpness and be of service. The trees would also be improved in appearance.

**Renewing Spurs.**—Should a difficulty be found in securing suitably placed buds, or those present are too weak in character to be encouraged, it is advisable to shorten back the whole spur, leaving nothing but an inch of bare wood next to the main stem. Strong growths will follow, but by early disbudding and a judicious course of summer pruning, those retained will eventually form fruit buds of the right stamp. Much good results by not taking these extreme measures, but gradually shortening back the spurs year by year, thinning out the weakest buds at any time when it is seen they can be easily dispensed with.

**Thinning Spurs.**—Attention must be given to regulating the distance between the spurs. A crowded condition leads to each cluster spoiling its neighbour, and is the main cause of unsightly elongations.

**Laying in Young Wood.**—Old trees may often be made fruitful by laying in and encouraging young growth wherever room can be found for such without crowding. Lay in all leading growths their full length where space is not fully occupied. Trees with rather long shoots having prominent fruit buds at their extremities may be tied in close to branches or spurs.

**Shortening Side Growth.**—Shorten the side growths or foreright shoots produced during the summer back to one or two buds at their base. On well managed trees these are plump, and promising to develop into sturdy fruit buds.

**Apples.**—Apples are treated when trained on walls in much the same manner as Pears. If anything the main branches require more room, and the majority of varieties should have them not less than a foot apart. The leaves of Apple trees are larger, consequently the expanse of foliage rightly belonging to one fruit bud is greater; hence there is more risk of the leaves overlapping and shading each other. Unhealthy foliage of Apples soon becomes a prey to red spider, which quickly reduces the vitality of a tree, rendering healthy development impossible.

**Pyramids and Cordons.**—These and other forms of restricted trees need similar treatment as regards thinning of branches, spurs, and buds, removal of weak and dead wood.

**Standards.**—Thinning out is the main operation which these require, but frequently a considerable amount of spray must be cut clean out from among the branches. Shortening branches is an evil to be avoided as a rule. It is necessary, however, when branches infringe on adjoining trees.

**Plums and Cherries.**—Two methods of producing fruitfulness on wall-trained trees are usually productive of good results. They consist of a combination of spur-pruning and the annual laying-in of young wood, which maintain trees in vigorous condition. Regulate all best growths, and re-arrange the main branches if necessary. Some of the shoots may be tied over bare portions of the strong branches, others nailed where space permits. Old bearing wood cut out freely to make room for the younger growths being thinly trained. They usually bear the second year. Morello Cherries are excepted from this dual method, they bearing only on growths of the previous year, which should be carefully tied or nailed in now or earlier.

**Preparing Trees for Grafting.**—Old trees intended to be grafted in spring ought now to have their main branches reduced to near the parts where grafts will be inserted, as it is not wise to behead large trees for this purpose when the sap is rising.

**Scions for Grafting.**—It is necessary to secure these early. The shoots are now dormant, and must be kept so until the time for grafting comes. Select healthy portions of the previous year's wood, carefully label, and bury them two-thirds of their length in a cool position behind a north wall, where they will keep plump until wanted.

**Forking among Fruit Trees.**—Fork over the ground, and bury manure between trees and bushes where there is no danger of injuring fibres or roots. The spade is a barbarous implement, as often thoughtlessly used amongst fruit trees and bushes.

## FRUIT FORCING.

**Pines.**—The plants recently started into fruit should be allowed a temperature of 70° to 75° at night, 5° less when cold, admitting air in the daytime at 80°; then allow it to rise to 85° or 90°, and close for the day at 85°. The bottom heat must be kept steady at 85° or 90° for Queens, other varieties 5° less. The plants will produce strong suckers if in good health. When the suckers are large enough to handle all, except one to each plant, should have the growths checked by taking out the centres of those not wanted.

Another batch of plants ought to be selected from those that have been wintered in 7 or 8-inch pots, choosing the most vigorous plants, and these will supplement the autumn-potted plants. The remainder of such plants should be reserved until the general spring potting, when they may be shaken out and treated similarly to the suckers then started. Good fibrous loam with the turf reduced, or if used fresh it should be placed where it can be heated, so as to kill the grass and any larvæ it may contain, and torn up in a suitable compost, adding a quart

of soot to every bushel, and a similar quantity of some approved fertiliser. Turf that has been laid up must be had under cover to become dried. Drain the pots efficiently, but not excessively, dusting wood ashes or soot over the crooks so as to exclude worms. Keep the plants well down in the pots, ram the soil firmly about the balls, and leave sufficient space for copious supplies of water being given when necessary. For Queens 10-inch and 11 or 12-inch pots are suitable for those of stronger or more robust growth. A temperature of 60° to 65° will be sufficient for these plants, also for those potted last autumn, and 80° to 85° at the roots.

If sufficient plants are started for fruiting late, successive plants that have not been subjected to a high temperature may be advanced slowly, they, with autumn-potted suckers requiring careful watering, especially where the heat at the roots is supplied by fermenting materials. Plants about to be started into fruit must not have the heat of the fermenting beds at the base of the pots over 90° or 95° or the roots will be injured.

**Figs.—Earliest-forced Trees in Pots.**—The trees being now in full growth, the points of the shoots must be pinched out when they have made about five leaves. A temperature of 55° to 60° at night, 65° by day, advancing to 75° with sun, closing early and allowing an advance to 80° or 85°, is suitable for the present. When the weather is dull give a little extra heat in the early part of the day so as to admit of a little ventilation if only for an hour or two to give a change of atmosphere and induce sturdy growths. The bottom heat should be kept steady at 75°, introducing fresh sweetened leaves and litter as necessary. Syringe frequently to keep the trees free from red spider, and always sufficiently early in the afternoon to allow of the foliage becoming dry before night.

**Early Forced Trees in Borders.**—The trees started at the new year have commenced growth; the temperature should be slightly raised both at night and by day, 55° being suitable at night and 60° to 65° by day, with a rise of 5° to 10° from sun heat and a free circulation of air, as a drawn and weakly growth cannot afterwards be rectified, and it should be avoided by ventilation on all favourable occasions, seeking a sturdy short-jointed growth from the commencement. Syringe the trees twice a day on fine days, but when dull morning syringing is sufficient. The border will need copious supplies of liquid manure in a tepid state, or waterings through a mulch of partly decayed manure and in a lumpy state, so as to allow the roots to have the benefit of the air. Avoid, however, making the trees exuberant, as that is fatal to fruitfulness.

**Second Early-forced Border Trees.**—Where there are several Fig houses a second may now be started, to afford fruit at the end of June and early in July. If the trees have not had the old bare growths cut out so as to leave the successive wood with its terminals for furnishing the first crop, and been dressed with an insecticide, these matters must have immediate attention. The border should be brought into a thoroughly moist state by repeated watering if necessary with tepid water, or where the borders are small and the trees large tepid liquid manure may be supplied. Syringe the trees twice a day in bright weather, occasionally only when dull, but damp available surfaces so as to secure a genial atmosphere. A temperature of 50° at night and 55° by day artificially is sufficient to commence with, advancing to 65° from sun heat, with a free circulation of air.

**Peaches and Nectarines.—Earliest House.**—Syringe the trees in the morning and afternoon to keep red spider in check, but an occasional syringing suffices in dull weather, damping the paths and borders instead of the trees, so as to maintain a genial atmosphere. Applications of liquid manure will assist the fruit in swelling, especially that on trees long subjected to forcing. Vigorous trees will not require any stimulants, excessive vigour being unfavourable to the fruit safely passing the stoning process. Proceed with the thinning of the fruit, removing a few fruits only at a time, those badly placed first. Follow up disbudding, leaving a growth at the base of each bearing shoot and another at its extremity, or at a level with the fruit. The shoots retained for supporting the fruit should be stopped at the second or third leaf unless they are extensions, but the basal growths must be trained to take the place of those now bearing fruit. Shoots upon extensions may be left at 12 to 15 inches apart to form the bearing shoots of the future. The night temperature may range from 55° to 60°, and 60° to 65° artificially, with an advance to 70° or 75° from sun heat. It is better, however, to seek advancement from sun heat and in favourable weather than to push the trees in sunless. Ventilate on all favourable occasions, and avoid a close, stagnant atmosphere at all times; but cold draughts are very pernicious, and aridity favours insect pests.

**Houses Started at the New Year.**—Continue to impregnate the blossoms, and when the fruit is all set a gentle syringing in the morning and at closing time will assist in removing the remnants of the blossoms. Ventilate freely under favourable external conditions. Maintain a night temperature of 45° to 50°, or 5° more in mild weather, and 50° to 55° by day, with an advance to 65° or more from sun heat. See that the border is properly supplied with water. Where the fruit is too thickly set remove that on the under side of the branches.

**Houses Started at the Beginning of the Month.**—Syringe the trees occasionally until the blossoms show colour, when it must cease; but a genial condition of the atmosphere should be maintained by damping available surfaces in the morning and afternoon, avoiding a close stagnant atmosphere. If the blossoms are too thickly placed thin them by running the hand downward on the under side of the shoots, which

strengthens the remainder, enabling them to set the fruit better. Ventilate at 60° and fully at 65°, closing at 50°, and only use fire heat to maintain a temperature of 50° by day and 40° at night. Trees started at this time will ripen their fruit early in July.

**Later Houses.**—Admit air freely so as to retard the blossoming, especially in the case of unheated houses, which are liable to suffer from spring frosts. See that the borders have water if needed. If the roof lights have been removed they need not be replaced until the buds are advanced in swelling, they are quite safe for another month or more.

**Melons.**—To secure a quick and sturdy growth there must be plenty of top and bottom heat, ventilating early on all favourable occasions, closing early with a genial atmospheric moisture on bright days. This will induce a consolidated growth, and that is essential to well developed blossoms, a good set, free swelling, and heavy fruit. Exercise great care in ventilating, a current of cold air crippling the growths, a piece of hexagon netting placed over the ventilators when the days are cold is useful. The temperature should be maintained at 60° to 65° at night or 70° when mild, 70° to 75° by day, and 80° to 90° with sun heat, closing early in the afternoon with plenty of atmospheric moisture on bright days, and if the temperature rise to 95° or 100° it will be more advantageous than otherwise. Sow as occasion requires for successive crops, always taking care to have more plants than are likely to be required.

## THE BEE-KEEPER.

### APIARIAN NOTES.

THE bee-keeper should not lose an opportunity in making sure that all appliances are in readiness for every emergency throughout the season. A little forethought will pave the way so as to steer clear of disorder and difficulties during the busy part of the year. By the time this appears in print the bees will have begun working on flowers or on the artificial product, pease meal. In every case where a shortness of stores is suspected feed liberally. During the latter half of January there were some mild days and nights, which were favourable for feeding bees. Where solid floors are in use change them frequently, so that damp during easterly March winds may not cause the bees to contract the cluster, and allow much brood to perish or eggs to be eaten out.

For upwards of thirty years the *Journal of Horticulture* has taught the method, and the advantage of having early and strong stocks. This is accomplished by preventing what your readers know as "bees going back," either by keeping the stocks well provisioned without feeding till June, or by careful and timely feeding those short of stores. It is therefore gratifying to see by the "Bee-keeper's Record" that the readers of that paper are profiting by our advice, inasmuch as the instructions given so often in these pages have been the means of producing a large yield of honey.

I may just remind your bee-keeping readers that hives with extra stores will, after breeding has commenced, not relax it so long as there are from 8 to 15 lbs. of honey in the hive up till June. But even with that amount of honey at that date, if the weather is inauspicious the bees will eat and draw out much brood and eggs. A hive with little or no stores may be kept breeding, but it is only by fits and starts, and but a small percentage of the eggs deposited are brought forth. If neglected to be fed for a short time thousands of eggs are destroyed. Stimulative feeding with short stores is time and money thrown away.

### COLOURED WAX.

I observe what "A Hallamshire Bee-keeper" says anent coloured combs on page 40. I have frequently mentioned the colouring of combs from flowers profuse in pollen, but never saw a case where the seals could be said to be coloured because of honey being gathered from certain flowers. The scales of wax when secreted by the bees are of one uniform whiteness, but not of texture or density. Bees have a tendency to imitate the colour of their combs to their surroundings within the hive, and that is one of the reasons why super combs are coloured when the centre of the crown of the hive is open, and the opposite when it is closed, especially when the combs are a year or more old.

As propolis is insoluble in water, I cannot think wax is coloured by it, but by pollen, which, if exposed to the sun, becomes white. I was once an eye-witness to a remarkable change in yellow wax becoming pure white by melting it a second time in a different water, probably caught from a new roof of corrugated iron.

I observe also "W. D." remarks on page 62, regarding Fennel being a good yielder of pollen, the latter being mostly used for the larvæ and for the seals of the brood cells, not for making them.—A LANARKSHIRE BEE-KEEPER.

## TRADE CATALOGUES RECEIVED.

J. E. Barnes, The "Great Eastern" Seed Stores, Norwich.—*Vegetable and Flower Seeds, &c.*

Richard Dean, Ranelagh Road, Ealing, W.—*Frimroses, Polyanthus, Hardy Plants, Seeds, Potatoes, &c.*

Dr. G. Dieck, Zöschen, Merseburg.—*Fruit, Trees, Shrubs, &c.*

Andrew Irvine, Tighnabruach, N.B.—*Pansies, Violas, Carnations, Roses, &c.*

J. Lambert & Sons, Trier.—*Vegetable and Flower Seeds.*

Pitcher & Manda, United States Nurseries, Short Hills, New Jersey, U.S.A.—*New and Rare Seeds, Plants, and Bulbs.*

Vilmorin, Andrieux & Co., Paris.—*General Seed Catalogue.*

James Yates, Stockport.—*Vegetable and Flower Seeds.*

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Manures for Roots (A. B.).**—A mixture of two parts mineral superphosphate, two parts steamed bone flour, and one part kainit applied at the rate of about 3 ozs. to the square yard, or 6 lbs. per rod, not deeply dug, but lightly pointed in now, would be good for roots after Brassicas, and after the plants appear top-dressings of soot would be very beneficial, as would nitrate of soda sprinkled on the soil only, not on the leaves of young Radishes. If you can procure guaranteed bone superphosphate the bone flour may be dispensed with. If you use nitrate of soda too freely and mineral support too sparsely you will soon weaken your land.

**Fungus Spoiling Mushrooms.**—Your beds appear to be infested with the most offensive and destructive fungus *Xylaria vaporaria*, referred to in "Mushrooms for the Million," page 94, sixth edition. After the strong and varied measures you have resorted to we fear there is small hope of anything banishing the pest short of thorough and complete disinfection extending over a considerable time. We are pleased to learn of your success in other than the infested building through following the instructions in the work named, and we expect if you abandon the old pest house you will not often be without Mushrooms, but will manage to grow them somewhere or other. All the same we are sorry for the infestation.

**Vines in Pots (Vine).**—We presume, though you do not say so, that you desire to fruit the Vines this year. If the wood you send is a fair sample, the Vines are too weak for affording a satisfactory crop, though they may afford small bunches. They could be supported in 10-inch pots with the aid of top-dressings and liquid manure, and would derive benefit if the roots could extend into a bed of mild fermenting materials such as leaves. We have seen good results accrue from shifting such Vines into larger pots when the work and subsequent watering have been carefully done. The time for shifting is when young growths push to the extent of an inch or two, only liberating the roots slightly as if repotting a Chrysanthemum. Nothing that you can do now can influence the production of bunches; but the berries of those produced may be enlarged by free-root action and adequate supplies of appropriate food.

**Gardenias (J. E.).**—It is just possible that the plants you cut back will not bloom this season. You kept them growing too late to ripen their wood sufficiently to set flower buds. Take out the points of the shoots and push the plants into fresh growth as early in the season as you can. They will then complete and ripen their wood early. This is necessary if they are to flower during winter. If the plants have a tendency to grow too long in summer, place them in a cool house fully exposed to the sun. They will then soon stop growth, and when returned to heat again will form flower buds. We have always been most successful by striking a number of cuttings in July or August in thumb pots, when well rooted placing them into 2½ or 3-inch pots for the winter. The shoots are pinched until they are placed in 5-inch pots, when they are allowed to extend until they complete their growth. A slight rest is given in a cooler house before they are introduced into heat. *G. Stanleyana* is very shy in flowering. You had better grow it as it is until it shows bloom. It requires to be well ripened. The flowers are single, white, very fragrant, and possess a very long tube.

**Orchids Unsatisfactory (T. O.).**—The plants appear to be in a very unhealthy state. The root-action is probably defective, and it is certain they cannot receive the requisite nourishment with the pots standing on either dry ashes or dry boards. If the medium in which the plants are, we will not say growing, but established, is sour, as it may be, it should be removed, and the roots washed and trimmed if needed, then placed in sweet material in small pots two-thirds filled with drainage, and the pots stood on a damp (not too wet) base. The *Dendrobium* growths were probably not well supported last year nor ripened. They cannot have too much sun in the autumn, and then need very little water. The temperature is suitable for most of the *Odontoglossums*. You should have explained the condition of the plants more precisely, also stated their size as well as the size of the pots, also the nature of the compost and roots, and when they were last repotted.

**Upright Cordon Pear Trees for House Gable (A Market Gardener).**—The following with liberal treatment would afford fine fruit:—Jargonelle, double grafted, August; Triomphe de Vienne, double grafted, September; Magrate, Quince, October and November; Doyenné du Comice, Quince, November and December; Beurré d'Anjou, Quince, December and January. Pitmaston Duchess produces grand fruit in such positions, and it is a pity to see cottage walls naked or occupied with worthless varieties of fruit trees, instead of the larger and better paying varieties. Pitmaston Duchess does well on the Quince, but better on the Pear stock. The Apricot would probably fruit better if it were root-pruned, and it should be attended to without delay, or deferred until the early autumn.

**Water-edge Plants (J. H. E. B. H.).**—The margins of artificial ponds or lakes are often bare, and not unfrequently monotonous from the natural or common-place plants that are employed to fringe them. If a greater variety of plants of different heights, varied habit, and diverse flowers were employed and disposed in irregular and bold groups, some near and some at a distance from the water, the distance between them being varied yet harmonious, good effects would be attained. The *Epilobiums* are fine; *E. angustifolius* thrives in rich moist soil, and grows 5 or 6 feet high, and has showy purple-red flowers. The Purple Loosestrife (*Lythrum Salicaria*) is a good water-edge plant; and *Spiræa ulmaria* (our Meadow Sweet) is excellent. The Reeds are indispensable. The common Reed (*Arundo Phragmites*), which abounds by river sides; Purple Small Reed (*Calamagrostis Epegoios*), attains to about half the height of the common Reed, has fine leaves and handsome plumes; and the Reed Grass (*Digraphis arundinacea*), with broad leaves and handsome plumes, contrasts well with the preceding. The last two grow 3 to 4 feet high, and the first sometimes 10 feet. Pampas Grass (*Gyncrium argenteum*) and the New Zealand Reed Grass (*Arundo conspicua*) succeed admirably, provided there is not an excess of water about the roots—that is, they must be planted high, and when dotted here and there are singularly effective. In the wetter places Lyme Grass (*Elymus giganteus*) and *E. canadensis* are suitable, and succeed where choicer plants do not thrive. Carexes do well in boggy places, none being better than our native species, *C. paniculata* and *C. pendula*. There is a variegated form of *C. acuta*, also of *C. riparia*, both doing well, even in water; and the Galingale (*Cyperus longus*) does well in shallow water. A Bamboo in conspicuous places add immensely to the effect. *Arundinaria falcata* and *Bambusa Metake*, with *Phyllostachys bambusoides*, are amongst the hardiest and best, and should be planted clear of the water. Club Rushes thrive in wet soil; *Scirpus triquetra* and *S. Holochænus* are both good. The Great Spearwort (*Ranunculus Lingua*) has bold foliage, showy yellow flowers an inch across, and should be planted close to the water edge. Sweet Flag (*Acorus Calamus*) is very desirable for its noble and aromatic leaves. The Water Plantain (*Alisma Plantago*) is bold and striking when planted on the margin of water; and nobler still is *Caladium virgicum*, planted in about 6 inches depth of water. *Caltha monstrosa* forms a mass of gold in early summer, and should be planted at the water edge. These, with those named in our former reply, judiciously employed would make a good assortment.

**Plants for Narrow Borders (H.).**—It is difficult to have some flowers almost all the year round from outdoor plants, but the following will afford a good supply over most of the year, as they bloom at different times:—*Aconitum pyrenaicum* 2, *Allium pedemontanum* 2, *Anemone appennina* 1, *Anthericum liliastrum* 3, *Aquilegia glandulosa* 2, *Armeria plantaginea rosea* 3, *Aster Amellus majus* 3, *A. bessarabicus* 3, *A. peregrinus* 3, *Aubrietia Campbelliæ* 1, *A. græca* 1, *Betonica grandiflora* 3, *Calochortus luteus oculata* 2, *Campanula dahurica* 3, *C. glomerata alba* 3, *Convallaria majus* 2, *Corydalis lutea* 2, *C. eximia* 2, *Cyclamen hederæfolium* 1, *Cyclobothra pulchella* 2, *Delphinium nudicaule* 3, *Dianthus fragrans* 2, *D. neglectus* 2, *Doronicum Clusi* 3, *Dodocatheon integrifolium* 1, *Erodium Manescavi* 3, *Erythronium dens-canis* 1, *Fritillaria meleagris* 3, *Fuchsia pumila* 3, *Gentiana acaulis* 1, *G. verna* 1, *Geranium Endressi* 3, *Helleborus atrorubens* 2, *H. niger angustifolius* 2, *Hepatica triloba* vars. 1, *Hypericum calycinum* 2, *Iberis corææfolia* 2, *Iris nudicaulis* 2, *I. caucasica* 2, *I. susiana* 2, *Leucojum vernum* 2, *Lilium Harrisii* 3, *L. tenuifolium* 3, *Lotus corniculatus plenus* 1, *Lychnis dioica rubra plena* 2, *L. diurna plena* 2, *L. vespertina plena* 2, *Muscari botryoides* 1, *Myosotis dissitiflora grandiflora* 1, *Narcissus bulbocodium album* 1, *N. Emperor, Empress, Horsfieldi* 2, *N. incomparabilis* 2, *N. nanus* 1, *N. obvallaris* 2, *N. poeticus ornatus* and *N. poeticus plenus* 2, *N. pumilus plenus* 1, *Oenothera Youngi* 3, *Omphalodes verna* 1, *Onosma taurica* 2, *Orobis vernus* 2, *Oxalis floribunda* 1, *Papaver nudicaule* 3, *Phlox subulata* and *alba* 1, *P. verna* 1, *Polemo-*

nium Richardi 3, Ranunculus aconitifolius plenus 2, Rudbeckia Newmaniana 3, Saponaria caucasica plena 2, Saxifragia Camposi 1, S. or Megasia ciliata, M. cordifolia, M. Stracheyi, all 2, Scabiosa caucasica 3, Scilla sibirica 1, S. bifolia 1, Sedum spectabile 2, Spiraea japonica 2, S. ulmaria plena 3, Trollius europæus 2, Tulipa Greigi 2, Veronica amethystina 3, V. prostrata 1, Viola suavis 1, and Zauschneria californica 3. In addition to the above you can have Alpine Auriculas 1, Pinks, both florists and mule 2, summer-flowering Chrysanthemums 3, double Daisies 1, Delphinium belladonna and the Globe 3, Iris germanica var. 2, Pansies and Violas 1, Violets in variety 1, Pæonies arietina decora and vars. paradoxa and fimbriata 3, Phloxes La Cour and Purple King 3, also Liberte and Mdle. Cuppenham 3, Potentillas 2, Primroses Harbinger, double crimson, lilac, purple; Giantess, white, yellow, rose, and sanguinea, Lady Isabel 1, also Polyanthus cærulea, Black Prince, Cheshire Favourite, and Zulu King 1; double and single-flowered Pyrethrums 3, which are invaluable for cutting; the indispensable Carnations 2, and Double Rockets 3. Then there are Snowdrops, Hyacinths and Tulips, with Anemone coronaria vars. 1, so that you would have a fair chance of securing flowers nearly all the year round. The figures refer to the rows—1, first row; 2, second row; 3, third row; but the border ought to be 4 feet wide, so as to give the plants a chance, or if you must adhere to 2 feet only use 1 and 2.

**Roses up Wellingtonias (Norfolk).**—The Ivy roots will probably have exhausted the soil, and it will be necessary to remove the largest, at least, of the Ivy roots and apply a good dressing of manure and mix it with the soil, so as to give the Rose tree a chance. If that cannot be done without injury to the Wellingtonia roots, it will be necessary to supply a good dressing of rich compost around the trees, say a yard wide all round the trees, and deep enough to plant the Roses in. Without some preparation of this nature it is probable the Roses would not succeed—possibly not then, especially if the Wellingtonia roots dry the soil considerably. As the Wellingtonias are bare of branches, it is possible that the Roses may succeed, and the following may meet your requirements:—Waltham Climber No. 1 is a good bright red Rose, and flowers till late in the season; Catherine Bell, deep rose, free flowering, and very sweet; Climbing Edward Morren, cherry-red; and Princess Louise, dark carmine shading to pink, or Setina, is a splendid climbing Rose, bearing a profusion of beautiful silvery pink flowers. Your other questions will have attention.

**Attar of Roses—Rose Water (G. P.).**—The attar is made from Damask Roses, Cabbage Roses, and Musk Roses, the first named in India chiefly, the others in Persia and Turkey. The attar of Roses is the oil of the Rose, which is procured by distillation, and varies in quality according to the quarter from whence it comes. From Dr. Jackson's paper in the "Journal of the Asiatic Society," we gather the following account of the manner in which attar of Roses is obtained:—"Round the station of Ghazepore there are about 150 acres of ground laid out, in small detached fields, as Rose gardens, most carefully protected on all sides by high mud walls and Prickly Pear fences, to keep out the cattle. Every beegah, or half acre, contains 1000 Roses, and if the season is good this beegah should yield one lac of Roses. The Roses come into flower at the beginning of March, and continue so through April. In the morning early the flowers are plucked by numbers of men, women, and children, and are conveyed in large bags for distillation. The native apparatus for distilling is of the simplest description; it consists of a large copper or iron boiler well tinued, capable of holding from 8 to 12 gallons, having a large body with rather a narrow neck, and a mouth about 8 inches in diameter; on the top of this is fixed the head of the still, which is nothing more than an old 'dekchee,' or cooking vessel, with a hole in the centre to receive the tube or worm. The tube is composed of two pieces of bamboo fastened at an acute angle, and it is covered the whole length with a strong binding of corded string, over which is a luting of earth, to prevent the vapour from escaping. The small end, about 2 feet long, is fixed into the hole in the centre of the head, where it is well luted with flour and water. The lower arm or end of the tube is carried down into a long-necked vessel or receiver, called a 'bhubka'; this is placed in a 'handee' of water, which as it gets hot is changed. The head of the still is luted on to the body, and the long arm of the tube in the 'bhubka' is also well provided with a cushion of cloth, so as to keep in all vapour. The boiler is let into an earthen furnace, and the whole is ready for operation. To procure the otto, or attar, the Roses are put into the still, and the water passes over gradually, as in the Rose-water process. After the whole has come over the Rose water is placed in a large metal basin, which is covered with wetted muslin tied over, to prevent insects or dust getting into it. This vessel is let about 2 feet into the ground, which has been previously wetted with water, and it is allowed to remain quiet during the whole night. The attar is always made at the beginning of the season, when the nights are cool. In the morning early the little film of attar, which is formed upon the surface of the Rose water during the night, is removed by means of a feather, and it is then carefully placed in a small phial, and day after day, as the collection is made, it is placed for a short period in the sun, and after a sufficient quantity is procured, it is poured off clear, and of the colour of amber, into small phials. From one lac of Roses it is generally calculated that 180 grains, or one tolah, of attar can be procured. More than this can be obtained if the Roses are of full size and the nights cold to allow of the congelation." Attar of Roses is said to be obtained in Macedonia by crushing the petals in mills, expressing the fluid part, filtering it, and then exposing it to the sun in small glass vessels. The oil gradually collects on the surface of the liquid, and is removed. There is also a manufactory of the article

at Florence which is conducted by a convent of friars. *Rose water* is obtained by distilling 1 gallon from 2 lbs. of Roses and 2 gallons of water. When properly prepared it has the delightful perfume of the Rose in great perfection; but it should never have alcohol added to it, as it is said to render it sour, by promoting the acetous fermentation.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Major Warfield*).—Good specimens of Golden Winter Pearmain, popularly but incorrectly known as King of the Pippins. (*J. F. D.*).—The Apple possesses all the characteristics of Bramley's Seedling, but we have not seen this variety so highly coloured as in the specimen you send. (*Alfred Brook*).—We suspect the Apple you send is of local origin, and never had a generally recognised name.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. T.*).—*Lycaste xytriophora*. (*H. F.*).—1, *Gleichenia circinata*; 2, *Acacia cultriformis*; 3, *A. melanoxylon*; 4, *Cocculus lauroleia*; 5, *Strobilanthes isophyllus*; 6, *Phormium tenax variegata*. (*Nareissus, G. W. R.*).—*Aurantius plenus* (Butter and Eggs), a variety of *N. inconparabilis plenus*.

## BASIC SLAG.

THIS useful addition to our phosphatic manures came prominently into use eleven years ago. It is known under the different names of basic slag, basic cinder, basic phosphate, and Thomas' phosphate powder, the last designation pointing to its derivation from the Thomas-Gilchrist process. Its low price and richness in phosphates has led to its use indiscriminately everywhere. For soils deficient in lime it is excellent; it may also be used advantageously on all soils, preference for a manure being influenced very much by its price. No doubt for soils containing plenty of lime ordinary mineral superphosphate, with an addition of pure dissolved bones, is preferable; but when the price asked is higher than that of basic slag, then slag is ordered. So it has come to be used very generally, and equally of course it has become adulterated so badly that in the new number of the Royal Agricultural Society's Journal attention is called to the necessity for analysis. In a case which recently occurred a guarantee of from 37 to 42 per cent. of phosphate of lime had been given, the slag to be of from 85 to 90 per cent. "fineness." On analysis the sample was found to contain only 31½ per cent. of phosphate of lime, and to be only 64 per cent. "fineness." Upon the purchaser complaining the agent through whom it was bought said, as the order was for so small a quantity, perhaps they did not think it would be likely to be tested. This was so, because another lot, ordered subsequently, came up to the guaranteed description.

The test for fineness obtained by thorough grinding is that 85 per cent. passes a sieve containing 10,000 holes to the square inch; and for quality that samples taken from the bulk correspond sufficiently near to the following full analysis:—

Lime	...	...	...	...	...	45.04
Magnesia	...	...	...	...	...	6.20
Ferrous oxide	...	...	...	...	...	17.56
Manganese oxide	...	...	...	...	...	3.17

Calcium		...	...	...	...	
Vanadium oxide	...	...	...	...	...	0.24
Silica	...	...	...	...	...	6.90

99.65

We commend this analysis to the attention of fruit farmers who may have become puzzled over formulæ of chemical manures in which certain quantities of iron and magnesia are said to be necessary in manure mixtures for fruit culture. They will then see that a liberal addition of basic slag gives them both these constituents, as well as the far more valuable phosphates of lime. Though it is certain that enough of iron and magnesia are almost always present in the soil as to render the matter of secondary importance in manure mixtures, yet to avoid vexation and uncertainty use basic slag; a little extra iron in the soil does no harm provided it has ample stores of nitrogen, potash, phosphoric acid, and lime, and it is certain that iron imparts brilliancy of colour to fruit. It is where soil has become permeated with oxide of iron by the ochrous deposit resultant from a chalybeate spring, that fruit trees canker. But even such soil may be rendered fairly suitable for fruit culture by the application of heavy dressings of lime.

For general use in agriculture basic slag ought certainly to hold a leading place; for permanent pasture especially it appears to be valuable. It should be applied early, preferably in the autumn, because it is more slowly soluble than some other phosphates; and it has this advantage, that while the growth of the year will only take up sufficient phosphoric acid for its requirements, soil retains the residue for the next or several

seasons of growth. A very common fault is the use of this and other chemical manures with too heavy a hand, from the popular idea that in manure richness and bulk are inseparable. No easy matter is it to enlighten the blind faith which regards a ton of farmyard manure as available plant food for the crop for which it is used, but it is possible to show how the action of basic slag, if slow, is persistent, till the residue in the soil is exhausted. The condition of the pasture is always a safe indication of its requirements, and it is not difficult to see when a second dressing of the slag is becoming necessary.

## WORK ON THE HOME FARM.

Advantage was taken of hard frost to cart manure from cattle and cow yards to heaps in the field intended for Mangolds. As each heap was finished it was quite covered with soil, and it will be so left till it is wanted next April; then as early in the month as possible it will be carted on to the land and spread along the rows just thickly enough to afford plenty of moisture for the plant in the earlier stages of growth. Though it contains some plant food there is not enough for the requirements of the crop, some phosphatic chemical manure being added to it before it is covered. After the crop is in full growth it has one or two heavy surface dressings of nitrate of soda, which, being worked into the surface by the hoes, dissolves quickly, so that the whole of the soil about the roots is stored with ample supplies of this rich plant food. The land intended for Mangolds was thrown up into ridges in the autumn by the double breasted ploughs, so that in April preparation for sowing consists in placing manure in the furrows and splitting the ridges, the sowing then follows at once. Here, again, we always find great benefit from thorough autumn tillage, both in having less work to do at sowing time and in the friable condition of the soil.

Supplies of chemical manures for spring work should now be procured from a reliable source, so as to be ready for dressing permanent pasture by the end of February. Where basic slag alone is to be used for the pasture, buy only under analysis, and apply at once. As it is best used in autumn, we should now mix with it about 1½ cwt. nitrate of soda per acre to promote prompt free growth this season. From 4 to 8 cwt. of the slag may be used per acre, according to the condition of the pasture. We may then feel assured that the residue of phosphoric acid in the soil next autumn will keep the herbage fresh and green during the winter, and then a moderate dressing of nitrate of soda alone will suffice in the following spring. All permanent pasture drainage is being pushed on, so as to afford time for the soil to settle down, the sods to be replaced, and pressed down by a heavy roller before spring. A few hours' rain or deep fall of snow causes the soil in new drains to settle down quickly; the sods can then be replaced at once, but if laid upon the soil when the draining is done they may fall over or be knocked about by horses or cattle.

## OUR LETTER BOX.

**Farm Repairs (J. H. E. B. H.).**—The matters concerning which you require information will be treated at length in our home farm articles, as they are of general use. You specify nothing uncommon in such work, but if subsequently to the publication of our notes you have anything for which you require special advice then write to us again.

**Small Farms - Past and Present Prices (J. J. S.).**—The information you wish can only be obtained after considerable research, if then, and therefore cannot be published this week. You have taken your time to ask the questions, and we must take ours to answer them. That is fair, is it not?

## REMARKS.

22nd.—Overcast throughout, with slight showers between noon and 3 P.M.  
 23rd.—Overcast early; sunny from 11 A.M. to noon; occasional drizzle between 1 and 3 P.M., and fair night.  
 24th.—Overcast early, fine during the middle of the day, but not sunny.  
 25th.—Fair, but sunless.  
 26th.—Overcast, and at times damp in the morning; showery from 2 to 3 P.M., and steady rain from 6 P.M. to 11 P.M.  
 27th.—Bright sunshine early, and about 2 P.M., but generally foggy, and dense fog from noon to 1 P.M. and 3 P.M. to about 8 P.M.  
 28th.—Fine, with occasional sunshine in morning, bright sunshine from noon to 3 P.M.  
 A mild week, temperature about that which on the average may be expected at the end of March.—G. J. SYMONS.

WE have been somewhat interested in a communication that we feel constrained to "bring to the front" from one of the old juveniles of the horticultural world—Mr. Robert Fenn of Sulhamstead. A warm-hearted example of a son of the spade and the pen is the writer of the notes in question. A curious mixture of pessimism and optimism appears to run through them, backed by a barrier of as fine crusted old Conservatism in social life and habits as the most loudly proclaiming "lover of his country" could wish to see. Yet, paradoxical as it may seem, this "*fin du siècle* Englishman," as he styles himself, claims to be in advance of all our modern reformers in having done years ago what they are trying to do now by lectures and cognate schemes, some of them, he would have us believe, working wrong end upwards. Perhaps he may be right, for there appears to be a tendency of desire on the part of at least some ardent aspirants to reach the top of the ladder in some more quick and easy way than in steadily climbing from the bottom. There is hidden wisdom in those references, and both lecturers and workers may do worse than ponder over them. They mean "begin at the bottom and work steadily 'upwards and onwards,' as I have done through years of persevering endeavour, and win by your labour as I have done a 'holding' that practically gives me all I need (except sugar) and makes me independent of the foreigner and all his works and wares."

A happy position truly, a well won arcadian home ; but there is a tinge of sorrow in his letter. It seems to suggest as if the writer had outlived his time and his friends, and that he feels a little deserted. He has, thanks to a well-spent healthy outdoor active life in work he loves, outlived many ; but many remain, and not a few of these would be glad if they could more frequently share his boundless hospitality and cheery companionship, even for a few hours during Potato time. We know that this is so ; but some of the ancients move slowly. They can no longer fly hither and thither in frisk Fennian fashion, as they would like. Let, then, this, the friskiest of them all, be thankful that he is not as those other men are ; but rest in the assurance that they rejoice in his strength and appreciate his work. But he has admirers whom he has not seen. Said one the other day, "If there is one man above all others I should like to see at home, he is Robert Fenn—the great herbaceous perennial I call him, who seems to die down for a while, then spring up as strong as ever." "Well," was the response, "if we are all well next July you *shall* see him." And so the compact was made ; and when our old friend sees his new one there will be an interchange of broad smiles and hearty greetings, to be followed by "something in the Journal" from a master in the art of husbandry and vivid description. And now, Mr. Fenn, be easy—at least, as easy as you can, and wonder who your new friend can be ; but in the meantime please step forward, and tell your mixed story to the world.

I have several things to say, but first I feel it has become due for me to write my experience of last season in respect to the anti-blight powder and Potatoes. I did not experiment with it so extensively as in 1891, and the crops that were operated upon I limited to garden culture, therefore I would refer to issues of the *Journal of Horticulture* for September 22nd, and September 17th,

1891, where my doings are commented upon by visiting friends. I consider myself as having been "sent to Coventry" in 1892, I was left so severely alone. Local people are very difficult to convince in the cases of anything new ; for instance, in a conversation with an estate agent, I happened to mention my then proceedings with the anti-blight powder, and I invited him to come and see the proofs of its action upon my Potatoes. He answered me, with a hauteur sufficient for an emperor, that "nobody could ever make him believe that any squirts with mixtures or puffings with powders would prevent the Potato disease." Probably this gentleman comes in contact with farmers or other cultivators of the soil on most days, and should their conversations take a turn like mine, of course a jump at conclusions would be the same. "A right one, too," you may think, for farmers, who usually cultivate those large coarse varieties chiefly for saleable market purposes, caring nothing for quality. These thick-skinned giants can take no disease worth mentioning, and the game would not be worth the candle to recommend the anti-blights for their field culture. However, it is not for them that I write. Magnum Bonum is still the most gentlemanly of their type, but, begging its pardon, I do not consider it a suitable garden variety.

It may be asked, "Then what do constitute a gentleman's or garden Potato?" I will answer, "Fenn's seedlings," and I think I write so for the first time. But it is becoming the end of the century to blow one's own trumpet. Then let the sound go forth. Sutton's Ringleader, Early Border, Lady Truscott, Rector of Woodstock, Woodstock Kidney, and Fifty-fold are six garden Potatoes (relieving the ground for second cropping) of the highest merit from any kind of soil. All of them excepting the first (that is a cross with my English pedigree stock and the true American Snowflake) are studied results from best English kinds, not to be procured now for love or money ; varieties crossed and re-crossed, and the blood of them, so to speak, handed down without a haphazard break through a long series of years. The above are quite enough for any parlour purposes, and there is none that can be grown having higher table qualities, or that contains equal sustaining powers ; and now, thanks to Tait & Buchanan's Anti-Potato Blight Powder, I can keep them perfectly free from disease if constantly dusted, so as to allow no loopholes upon the foliage, for the fatal spores to take possession. I had the above varieties along with other of my newer seedlings grown purposely in the garden for testing the powder. Not a leaf took the spot, nor did a single tuber become diseased ; and what is more, I had the store tubers overhauled purposely last week to give the latest tone for this call, and to find an entire bill of health. "Not an unsound Potato amongst them," which cannot be claimed for those which were not operated upon, either in their growth or afterwards.

Now, what am I to conclude from this? I should have been pleased for you and your scientific people to have come and witnessed the results, as well as other foremost men of light and leading now amongst you, who at one time of day would not have wanted pressing. I seem to consider the above application of far more importance to horticulturists than the sloppy mixtures, unless peradventure the wet can be subtly dispersed in the guise of dew. I think I have improved upon the Malbec bellows more simply in regard to the application for Potatoes—viz., Procure a fine hair sieve, or horse's-bait sieve, with a piece of fine muslin secured upon the wickerwork mesh, first having fastened a forked stick to the bottom, allowing a sufficiency of stem to serve for a handle ; suspend the sieve by the left hand over the Potato haulm, walk rapidly by the side of the row, and keep tapping the rim or side of the sieve with a short piece of stick, and please yourself whether to perform so again, or with the bellows. I never rode post for a patent, so there you are.

I have other reasons why I should have liked to receive a visit from you men of mark last season, because much advice is

booming in all directions anent "small holdings" and "allotments." Titled advisers, lectures here, and lectures there, many of them beginning from the "top stave of the ladder" in lieu of issuing from the bottom rung. I suppose my 15 acres may be called a "small holding," and my chief reason for coming to it was to enable me to end my Potato experiments in peace without a chance of being turned out or having to dodge backwards and forwards to Bedford in Middlesex, as I was obligated to do when I lived at Woodstock. I had fairly worked to the end of my tether here in improving our chief important esculent for food, when in came the fashion for monstrous tubers, to which I would not submit myself. It caused me, however, to resort to draining and levelling my land for planting fruit, forest, coniferous, and other trees, and to lay the chief of my arable to grass, with addenda for farm and house sewage, cowhouses, stable, barn, and sheds. It may be easy to lecture about "small holdings" and other things, but I do not often learn about expenditure. The above necessary improvements meant for me £1500 at least, with years since of waiting before much recoupment could be reaped for the outlay.

Pray do not wake up, sir, by suspicion that I am trying to wheedle you into politics! What I want to say is so intimately connected with the culture of our soil, that I hope you will allow me to explain that I am an Englishman, consuming my own produce, which I have in the main created, living on and out of it, and residing here long enough to behold it as a living grown-up *fin du siècle* lecture. I will not eat or use a particle that is foreign more than I can possibly help. I drink no beer because of the foreign malt, and eat scarcely any bread—or the compound that is called bread—because of its fabrication from foreign flours or mixtures; my Potatoes are far more nourishing. I would eat bread made from hearty English Wheat flour if any farmer near me would grind it. I have my own fed (chiefly upon my Potatoes) and home-cured bacon, poultry and eggs galore, home-made butter, and plenty of honest milk, home-made jams of all kinds—my "missus," you know, was taught her cooking at Her Majesty's School, Windsor Great Park, some forty to fifty years ago—home-made wines and cider; fruit, all the year round, beginning with green Gooseberries and ending with Wellington Apples on the same advent; in fact, we are nearly vegetarians; but when I do treat my family to a joint of fresh meat, I send to our local butcher and put him upon his honour to let me have a joint of bred and fed English mutton. I never became intoxicated; I never smoked a pipe of tobacco, a cigar, or cigarette in my life; and as I strike seventy-six to-day (February 1st) I do not intend to begin. I do an honest day's work of from twelve to fourteen hours, rarely missing, and I do not remember ever having to call in a doctor, which proves that the above system of living cannot be far wrong. You may say, "What has your system of living got to do with the readers of this paper, or with us?" Well, a mere old woman's bagatelle—let me say "a drop in the sea." But if millions of one's countrymen, not necessarily "small holders," would be patriotic enough to do as I do in their systems of living, and favour hearty English produce, it would prove a very good other side to the question, in affording a natural relief for the depression of our home industries, and also spur on the re-cultivation of our native soil; something more universally substantial for us than bothering at present about "Protection." That, I presume, will have to come from below, when the majority of us become "small holders," to find out where the shoe pinches. This may safely be deferred till—say the Greek Kalends.—ROBT. FENN.

## HARDY FLOWER NOTES.

### LYCHNIS CHALCEDONICA FL.-PL.

THERE are few flowers of summer possessing more brilliance than the double scarlet Lychnis, *L. chalcedonica* fl.-pl., known in olden times as the Double Scarlet Flower of Constantinople, or Nonesuch. A native of Russia, it probably came to us from the

City of the Golden Horn, whence in all likelihood it derived its popular name. The origin of the specific name is said to have been due to seeds of the single variety having been brought from Chalcedonia. The name Lychnis is derived from *Lychnos*, a Greek word signifying a lamp, and considerable discussion has taken place as to the sense in which the word has been applied to the flower, some considering that the downy leaves of some of the species were used as wicks for lamps; others that the inflated capsules resembled a lantern; and others, again, holding the opinion that the name was applied in consequence of the flame-like colour of the flowers. However this may be, there is no question that the last opinion would receive ample countenance from the flower under notice, for even in the brightest days of summer, when flowers seem to glow with colour, and when Nature has put on her most gorgeous floral attire, the double scarlet Lychnis stands conspicuous with its shining blooms. In Parkinson's time it was comparatively rare, and that true admirer of flowers describes it as a glorious flower. In after times it became more plentiful, and then the tide turned, and the ebb-tide of fashion carried the Nonesuch into comparative obscurity. Such a flower could hardly remain long neglected, and it is now more frequently met with, although still too rare. It is seldom, too, that we see it as it should be grown—i.e., several plants together; but more frequently a solitary specimen with a few heads of flower is what is found. It cannot be said, however, that the beauty of the plant is thus properly seen. The Chalcedonian Lychnis is stiff in habit, and lends itself better to grouping than to growing as a solitary plant. Place half a dozen plants together well back in the border in rich soil, and the result will be that they will make a notable feature in the garden.

The double scarlet Lychnis, although not what may be called a high-priced plant, is not a cheap one, and it may be well to indicate the method of propagation which was more largely carried on many years ago than now. Division of the plants in September may be adopted where they are large enough, but the best method is to take cuttings of the lower parts of the flower stems in July. There should be three joints in each cutting, and two of these should be beneath the surface. If watered and shaded these may be placed in the garden, but it is generally safer and more convenient to put the cuttings in pots and place them in a greenhouse or frame.

The double white Chalcedonian Lychnis is but seldom met with, a fact which is probably due to the greater popularity of the double form of *L. vespertina*, a most valuable flower. *L. chalcedonica* alba pl. is not equal in value, but unless the collection is necessarily limited it should find a place also. Three feet is about the ordinary height to which *L. chalcedonica* will attain.

### SERRATULA TINCTORIA.

In sharp contrast to the splendour of the double scarlet Lychnis is *Serratula tinctoria*, the Dyer's Saw-wort, a plant about which I have had some hesitation in writing.

The inclusion, however, of a bunch of the typical species and one of the white variety in a first-prize stand of twenty-four spikes or bunches of hardy herbaceous flowers, and the fact that I have frequently met with the plant in gardens as a *Centaurea*, leads me to think that a notice might be of some value. It may be as well to state that the prize stand was in competition with six or seven others from large gardens in most of which hardy flowers are largely and admirably grown, and also to make it quite clear that, although not personally interested in the show, I am not to be held as endorsing the award. So little known are the *Serratulas* that I do not recollect of meeting with any other plants of this genus in any private garden, and, with others, I have made many searches into descriptions of the *Centaureas* in hope of finding the name of this plant. It is undoubtedly, however, what Philip Miller describes as "*Serratula vulgaris flore purpureo*," the "common Saw-wort with a purple flower," the white variety being "*S. flore candida*."

Miller's description of the *Serratulas* is an admirable one for those who are not adepts in botanical terms, and when I say, as Miller says of the genus, that *S. tinctoria* "differs from the Knapweed in having the borders of the leaves cut into small, sharp segments resembling the teeth of a saw," a fairly accurate idea of the appearance of the plant is being given. I think, too, that Miller went near the mark when he said that this plant was seldom admitted into gardens, but that as a plant which would grow in the closest shade it might be placed under trees where it would thrive and flower extremely well, and add to the variety. This seems to be the plant now known as *S. tinctoria*.

It may be thought that too much space has been occupied with the *Serratulas*, but in view of the recent discussion on judging herbaceous flowers, and also from the knowledge that

many are in search of its name, I fancy it may not be out of place to speak of it now.

#### CAMPANULA LATIFOLIA ALBA.

A plant of a different order of merit, although a native also, is the white form of the Broad-leaved Campanula, *C. latifolia alba*. This is a flower which can be recommended with every confidence, although the genus is a large one, embracing many beautiful plants. I think, however, that this one should not be overlooked, although it is only fair to say that it is rather widely met with in cultivation. It grows from  $2\frac{1}{2}$  to  $3\frac{1}{2}$  feet in height with me, and is usually much admired, its long, pure white bells in long spikes being very attractive, while the serrated leaves are very pretty also. I had some flowers of this variety brought me from a wood in this neighbourhood (Dumfries) which seemed more clustered on the flower stalk than the variety in my garden. I hope to have an examination of these wild plants next season, as there may be some good forms discovered.

I have frequently observed plants in catalogues offered as *C. macrantha alba*, but have never yet seen a true white variety of the splendid *C. macrantha*, which is believed to be only a varietal form of *C. latifolia*. I have also communicated with many hardy plantmen on this subject, and nearly all agree with me that what is grown and sold as *C. macrantha alba* is only *C. latifolia alba*. I met with what was described as *C. m. alba* last autumn when in Renfrewshire, and was assured it was true to name. I have a piece of the plant, which was out of flower, but from comparison with *C. macrantha* which was growing beside it I could not refrain from stating that I adhered to my opinion, although I am open to conviction. No one who has seen the true *C. macrantha* in flower will ever confound it with *C. latifolia*.

#### VERONICA SPICATA VERA (?)

Troublesome as regards nomenclature as are many genera of hardy flowers, there are few more so than the Veronics. One pink-flowered form has given me an endless amount of trouble, and although I have several names for it as grown in botanic and private gardens I do not feel confident that I have a satisfactory name as yet. I suppose most people will think, however, that *V. spicata* is so well known that there can be no dispute about it. It is, however, a variable species, and among other things it varies much in height, not only from the conditions of soil and climate but also naturally.

In the course of my wanderings among gardens I came recently on a small dwarf form, growing about 8 inches in height, and a very beautiful dark blue variety it is. It was grown as *Veronica spicata vera*, but has no more claim to the distinction of the name *vera* than any of the others. *Pumila* or *nana* would be more correct. Whatever name may be given to it, this is a very pretty little plant, and should be secured if possible, the short but good spikes of dark blue flowers rendering it very attractive, while its dwarf habit makes it exceedingly suitable either for the rockery or the front row of the border. It is a fitting companion to such dwarf varieties as *V. nummulariæfolia*, *V. prostrata*, or *V. corymbosa*. —S. ARNOTT.

### INSECTS OF THE FLOWER GARDEN.

(Continued from page 569, last vol.).

MERRY and joyous, to appearance at least, are the flies that belong to the family of the Syrphidæ. They are familiar objects in our gardens, and also about fields or woods, all of them lively in their movements, and many remarkable for their musical hum, though some are silent. Various are their shapes and sizes; several species much resemble bees, others have a compact look, but a rounded abdomen, others again exhibit long and narrow bodies. A few of them have the thighs curiously swollen, so that it might seem they were insects of leaping habit. A noticeable peculiarity of all is the convex head, flattened behind, the face often appearing nearly covered by the eyes, which are very large in some males; the tongue is usually bent in the middle, and has powerful muscles. Several species are amongst the blood-suckers, attacking both men and animals, but the puncture they make is not followed by the irritation which attends the bites of the gnat tribe. Some of them have heads brightly metallic, and their bodies are mostly banded with two or three colours, black being one of these; a few species are quite black.

With regard to their visits to flowers, the gardener has nothing to apprehend; possibly these flies may now and then prey upon smaller insects, but they do not damage the petals of flowers, though some bees are suspected of doing so. In the larval state many of them are really of notable service to us by their diligence in clearing off some of our garden pests, but one or two species that lead a subterranean life must have a bad character given them. A species

that darts from bed to bed in the garden so rapidly that we seldom get a good view of it has an oval abdomen, which is white and horny, translucent almost as it were of glass. Lacking an English name, we must give it the Latin one of *Volucella pellucens*; the larva or grub has its abode in the nests of humble bees, also of wasps, where it devours the young brood. A curious thing is, that these insects do not interfere with the intruding fly grubs; perhaps they are half afraid of meddling with them, for the larva of a *Volucella* is a singular object, in form like a rolling-pin, having a very small head and a body wrinkled and studded with points. Another species, *V. plumata*, has a near resemblance to the worker humble bee, being clothed in yellow, black, and grey; its antennæ are also feathered. The flies in the genus *Syrphus* are sometimes called Hawk Flies, the reference probably being, not to the carnivorous habits of the larvæ, but to the way in which they hover over flowers. Their habit is to poise in the air seemingly motionless, then make a sudden dart in some direction, and stop again, rapidly vibrating the wings when they do this. It is a fact not yet explained that there are years during which the hawk flies are abundant while in others few are to be found. Parties of them have been seen on the south-east coast of Kent, of several species mixed, which seemed to have crossed the Channel. *S. lucorum* frequents both groves and gardens; it is a pretty fly, chiefly black, but having a few patches of brown and yellow. Some naturalists have watched the mother fly of this species busy at the operation of laying eggs; these are placed, one by one, amongst the crowds of aphides, which, in spite of precautions, are sure to occur upon the leaves or shoots of various plants and shrubs.

A *Syrphus* larva has a pointed, leech-like head and a blunt tail, by the help of which and some tubercles it travels along, when it requires to make a change; usually it moves but little, finding plenty of food around. Most of the larvæ of this genus subsist upon aphides, and their method is to hoist each victim in the air by means of the mandibles, suck its juices, and let it drop. The growth of such larvæ is rapid, and when full fed each secures itself to a leaf, and a singular alteration occurs, as it becomes a pupa, the head thickens, and the tail becomes thinner, the larval skin forming a sort of cocoon. There is a little lid at the top, which the emerging fly pushes up, and departs to its life in the realm of air. One species, *S. pyrastris*, ought to have the special regard of admirers of Roses, as its particular food during growth is the aphides of that tree. It is a handsome fly, blackish-blue with a shining thorax and banded abdomen, covered by down of a light grey colour, or sometimes golden. From the way in which many of the aphid-hunting larvæ move their heads when they are in search of their prey, it is presumed they are blind, and discover it by the sense of touch. One of the hawk flies, however, is called the striped Onion fly, a little insect, prettily marked, but its progeny is a bristly grub, occasionally unearthed in the kitchen garden, where it is obnoxious to the Onion, also to the Carrot.

We have a rather brightly coloured but oddly shaped group of flies in the genus *Conops*, which resort frequently to flowers, not very correctly named either, for the word in the Greek means a gnat, or a gnat curtain; we have it also in our English word "canopy." These small flies are harmless in their perfect state; the mouth has no lancets, only a stiff proboscis; and honey is their food. Excepting in the form of the abdomen they have a decided resemblance to the solitary wasps, that make burrows in Rose or Bramble shoots and in decayed wood. As larvæ, it is presumed from the habits of some that the others are also parasitic; the larva or grub of *C. vesicularis* has been detected in the bodies of humble bees. The insect lives till full grown thus hidden, and then works its way out between the segments of the bee to become a pupa. It is remarkable that this curious resident in the bee's anatomy manages to avoid touching a vital part, for it survives usually the departure of this parasite for a short time. This particular species is black, red, and yellow; the wings are tinged with brown. Another pretty species is *C. flavipes*—a thin-bodied fly, black and gold. *C. rufipes* has the appearance of a miniature hornet. A rarer species occasional in gardens is called, from its largish head, *C. macrocephalus*. Its general colour is black, the head being yellow, and yellow streaks appear on each segment, the thorax having two silvery spots; the wings are yellowish, and the legs red; altogether a singular insect. How these flies manage to get their eggs deposited upon the bees they infest remains a puzzle.

An insect in this family that is an exception to most of them in habit is the Narcissus fly, or *Merodon clavipes*, these Latin names meaning "thigh-toothed" and "club-footed," for at the inner side of each thigh there is a strong tooth, and the hind legs are thickened or club-like. It is adorned with grey and golden hairs on the black ground colour, and visits flowers about April or May, having passed, singular to say, nearly a year in the pupal condition which few flies do. The grub or larva of this fly is a

round object, ringed with short hairs, the mouth being noticeable by two scaly hooks which project from its sides. Probably the mischief this larva does is partly attributable to the exudation from the body, which is of a slimy nature; by its mode of life it is hidden from view within the bulb, which it quits to enter the earth. The discovery of the pupæ amongst soil is not difficult, and they should be sought during autumn. This fly also visits other bulbous plants cultivated in gardens. — ENTOMOLOGIST.

### MARGARET CARNATIONS.

THESE beautiful flowers have in my opinion fully merited the high encomiums bestowed upon them when first put in commerce. Various opinions have from time to time been expressed, and, as might be supposed, their good qualities do not seem to fully satisfy all classes of cultivators, for it is scarcely possible that any race of plants, however good, will achieve that distinction when individual tastes, inclinations, and desires differ so much. I thoroughly believe, however, that an increasing number will ere long find out their great value, and will welcome them as a grand addition to late summer and autumn flowering plants. It is during that period that their usefulness is especially apparent. The ease with which they are grown, the comparatively short time which elapses from the sowing of the seed to the flowering stage, and the many beautiful shades of colour to be found in the flowers, combined with the good qualities previously mentioned, will assuredly secure for them great popularity.

Last season I obtained a couple of packets of seed from Messrs. J. Veitch & Sons. The seed of one packet was sown about the middle of February, and the other the first week in March, the latter sowing being made in a cold frame, and the former one in a pit, the temperature of which ranged upon 45° to 55°, in which position the plants were kept until growth was well advanced. The last week in April they were transferred to cold frames, and during the last week in May planted in mixed borders in the open air. From this sowing a few flowers opened in July, but flowering was not general till the middle of August, and continued to a limited extent till the end of October. The flowers seemed to withstand the vicissitudes of climate far better than many autumn-flowering plants, the heavy rains apparently having a less injurious effect upon them than upon Michaelmas Daisies. At the end of October many plants had still numerous well formed buds upon them. The best plants then were carefully lifted, placed into 5 and 6-inch pots, and put in a house which was given no more heat than was necessary to exclude frost. Very few buds were lost through the check experienced when lifted. These plants now look healthy and well, the buds showing every sign of affording useful flowers at the advent of warmer and brighter days.

The plants resulting from the March sowing have been kept in pots, and have proved of the greatest value. They were stood in cool frames till the beginning of June, and then placed in an open position out of doors. Shortly after this date they were placed in pots ranging from 4 to 6 inches in diameter, in which they flowered, the compost used being two parts loam, one part manure from a spent Mushroom bed, with a little sharp sand and soot added. A shady position was then given for a fortnight, during which time the plants were syringed freely twice daily. After this, they were again arranged thinly on a bed of coal ashes in the open air, and received a thorough syringing during the afternoon of fine days. This syringing is an important item in their culture, as it keeps them quite free from the attacks of green fly, and forwards their growth wonderfully. These plants afforded a number of flowers during the autumn months, and they are again beginning to open their buds. I have no doubt flowers might have been obtained throughout the winter if the plants had been given more heat.

In regard to the form and substance of the flowers obtained I may say they have varied greatly, but only a very few quite single ones were produced; some were good full flowers, quite equal to many border Carnations of acknowledged worth. The majority, though somewhat small, were of a sufficient size to be thoroughly useful for a variety of purposes in a cut state, and the flowers were so freely produced, and withal so deliciously scented, as to prove invaluable for room embellishment when left upon the plants.

A great variety of colours were obtained, the pink and rose shades being especially good. One variety, which I intend to propagate freely, has flowers of a more pleasing shade of colour than the well known Raby Castle border Carnation. I venture to predict that these Carnations have a great future before them, for with but little trouble they supply an abundance of beautiful and scented flowers at times of the year when they are especially valued, and as a stock for the hybridist to work upon they possess advantages not to be found in any other race of allied plants.—H. DUNKIN.

### THE ROSE DERBY.

SOME of your readers may possibly be pleased to know that I have recovered the shock received on reading the Rose column of the "Journal" of the 2nd inst. As to the "friendly criticism" published therein I reply shortly and seriatim to the numbered statements.

1, To use a sporting metaphor, suitable to Mr. Pemberton's heading, he has made a false start. Although not a planet of acknowledged brilliancy, and "constantly on the move" since 1877, I yet claim to be a star of the fifth magnitude (which is the smallest size visible to the naked eye), and of 1878 *that* (and not 1889) being the year of my first appearance in the firmament of the N.R.S.; Mr. Benjamin Cant of Colchester being my first instructor in the culture of Roses.

2, I am proud of the success my most diminutive garden has achieved. I do not deny it has merits, and I hope I have not unduly, or at any time, magnified its performances; its fault *is* its size, its drawback its position, of beauty it has none.

3, I neither have the wish nor the intention to turn a real pleasure into a business, and therefore even if I had the space I should not be in the least likely to grow maidens.

I could enlarge on this subject of growing maidens, but refrain from doing so out of respect for the amateur rosarian body in general. I have not the time to go all over the north country visiting Rose shows, nor can I see any advantage I should gain by such unnecessary trouble; our southern amateurs' and professionals' gardens and exhibits give me all the Rose education I am evidently sadly in need of. But I would ask this question, If the northern and midland growers, with the notable exception of Messrs. Harkness & Sons, are so superior in the latter half of July, why is it they do not enter the lists and try conclusions with Mr. B. Cant, Mr. F. Cant, and Mr. George Paul at the provincial shows? And to point the question, I instance the Show at Chester in 1892, when their Roses not only should have been but were in excellent form.

In conclusion, I leave the whole question as it is clearly put by your correspondent, "D., Deal," who ridicules the assumption of virtuous claims made by certain gentlemen writing nominally on behalf of the rosarians of the midlands and the north, but in reality playing for their own hand; and "D., Deal's," arguments being really unanswerable, I consider our position impregnable, at all events until the northerners have champions who can plead their cause in a more reasonable, accurate, and common-sense way.—CHARLES J. GRAHAME,

### NATIONAL ROSE SOCIETY—JUBILEE TROPHIES.

I HAVE inadvertently made a mistake with regard to these. I did not intend to include 1892 in the list of winners, and wronged my old friend, Mr. B. R. Cant, by omitting his name. The list ought to be: Nurserymen, 1887, 1888, 1889, 1890, Messrs. Harkness & Son; 1891, Mr. Frank Cant; 1892, Mr. B. R. Cant. Amateurs, 1887, 1888, Mr. T. B. Hall; 1889, 1890, 1891, Rev. J. H. Pemberton; 1892, Mr. J. P. Budd. This more correct list does not affect the point I intended to elucidate—viz., that the southern amateurs have taken the lion's share from their northern brethren.—D., Deal.

### THE NATIONAL ROSE SOCIETY.

IT should be a matter of congratulation to Mr. Grahame and myself that we have "drawn" "D., Deal" (page 89), who even in a private capacity speaks with authority and experience. I quite agree with him that it is highly satisfactory for the Society that we have a Secretary who is not an exhibitor, and yet kindly devotes so much of his time and experience to the matter. A secretary who does not exhibit is as much more suitable to a Rose society than one who does as a non-playing secretary in a cricket club is to one who does play, provided in both cases the enthusiasm can be kept up. But in such a cricket club the secretary should in some matters take counsel with the playing members, as they will have more knowledge; and so it should be in the N.R.S., which has ordained that its most trusted temporary officials, the Judges, should be chosen from successful exhibitors only.

I, too, think it high time that those who "write so loftily of arrangements" (I do not feel very guilty) should know that, according to "D., Deal," "we are quite dependent upon the Crystal Palace Company for having any metropolitan show at all." It certainly seems a very poor and subservient position for such a Society as the N.R.S., and I hope every member will take it to heart, and by diligent inquiry, hard thinking, and hard working do his best to devise a way for our delivery from such fetters. I am surprised that Mr. Head should complain of "great gaps." Is not every secretary of a Rose show in a state of preparation for gaps, ready to put the boxes a little way apart, and if necessary to fill up really "great" gaps with pots of flowers or foliage, or something? And surely Mr. Head's complaint of gaps should not be of much moment in comparison with that of an exhibitor who has "paid his money," but cannot find any place, much less "take his choice."

I am sorry to hear that it is "a very idle matter to compare the arrangements of a great show at the Crystal Palace to any provincial

one" when the said comparison is to the discredit of the former, and I am sure the members of the N.R.S. will agree with me.

It is not wise, as a rule, to say "the cap fits;" but the picture of an exhibitor who, on being asked to clear out, folds his arms and steadily refuses to do so until he gets a place for his box," does, I admit, represent me fairly enough. Whether it will be a faithful likeness of my attitude on July 1st, 1893, depends, I now understand, entirely upon the Crystal Palace Company and Mr. Head.

"D., Deal," next reflects sarcastically on the "virtuous claims" of the advocates of a later date. He applies a simple "tu quoque" to my statement that I heard no reasons put forward by the advocates of an early date except that their own Roses would be over at a later one; but he does not notice the concluding part of the same sentence, "that the supporters of Mr. Pemberton's motion had so many arguments of all sorts that the time would not suffice for them." This denied the "tu quoque" beforehand, and Mr. Pemberton's letter on the same page as his own sufficiently disposes of this weak rejoinder.

"D., Deal's," next two arguments seem to me to prove just what he does not want them to do. He actually takes up the cry raised at the general meeting of the fewness of northern members, apparently as a reason for not taking them into consideration, without seeing that it is *because* they have not equal privileges with others that they are so few in number. He then goes on to show of the Provincial Exhibition that "the Jubilee and most of the principal prizes have gone to Essex, Somerset, Gloucestershire, Herts, &c.," and does not see that this proves that a later date suits all these counties as well as northern ones.

With all that he says upon judging I quite agree; it would be impossible, even if advisable, to judge the medal Roses after the classes. But I am surprised that Mr. Grahame (on the same page) does not know that a knowledge of Roses as grown on different soils is desirable in a judge. Has he not noticed, when visiting the gardens of other growers, certain marked differences in some varieties as grown on different soils? For an instance or two: my plants of Beauty of Waltham are fine, to all appearance it "does well" with me, yet Mr. Pemberton's blooms of the same variety are not only better in size and colour, but there is also apparently a difference in character, and it would require experience to know that the variety is true in each case. Prince Camille de Rohan, nearest to black on a good Rose soil, will only come deep crimson, quite different in colour, in some other places. And who but Mr. Prince can show Comtesse de Nadaillac successfully in the class for yellow Roses? I have had the medal first two or three times at least, but it is always more pink than yellow with me. These are but examples of the many idiosyncrasies among Roses. How then can a man, merely from a study of his own garden, though it be as minute as possible (the study, not the garden!) expect to equal in experience a wider observer?

I agree, however, with what Mr. Grahame says about giving no points to moss, &c., if possible, but we are bound by the rules, which (v. 5) say, that in case of equal merit in blooms we should consider other details. In such instances there would have to be a large discrepancy in all these matters put together to prevent my judging the stands as equal, in all cases where the prize can be divided; but where there is a cup or trophy one must decide if possible. In the best prize (cash) I tried for last season the Judges declared my blooms and my opponent's to be equal, but gave him first because his blooms were "a little" (their words) better set up.

As to the question of proxy voting, "D., Deal's," objections seem to me ("naturally," he will say) to be answered by my remarks immediately opposite; and his principal argument (well illustrated by the story of the cart before the horse—I mean the collection before the sermon) to be met by a sentence of his own at the commencement of his letter of two columns, where he says that "he does not suppose that anything he will write will have the least effect upon any of the disputants." It is not denied that voting in person is best, but it is argued that proxy voting for members at a distance is better than so taxing their votes as practically to disfranchise all but those with plenty of money and leisure.

But bearing in mind what has been said, and without in any way committing myself to it, how would the supporters and opponents of proxy voting like this compromise? "That at a general meeting, voting by proxy shall be allowed on any subject which has been debated at a previous general meeting." Let it be understood that I ask the opinion of members of the N.R.S. upon this matter "without prejudice," or promising to give up the original motion.—W. R. RAILLEM.

#### NATIONAL ROSE SOCIETY.

A LINE of congratulation, Mr. Editor, upon the "rosy" character of your last issue. My good friend, Mr. Grahame, has met me several times during the last few months with the lamentation, "How is it there's nothing about Rose matters in the *Journal* now?" but I think the last number will satisfy even him.

#### THE METROPOLITAN SHOW.

"D., Deal," claims great advantage from the fact that in discussing this matter he speaks as a non-exhibitor, but he seems to forget that

there is another side to this question, and one which rather tends to discount anything he may say upon the matter. The rule of the N.R.S. concerning judges is, "They shall be selected principally from successful exhibitors," and this rule was adopted because it was felt that those who were not at the present moment exhibiting as well as growing were not in a position to correctly gauge the merits of the flowers staged. The same reasoning may surely be fairly applied to such a matter as the best date for the Show, and so your correspondent is put out of court upon his own ground of not exhibiting.

"D., Deal," then goes on to say that "Since the retirement of Mr. Whitwell and Mr. T. B. Hall we have no amateur grower of the first class in the north;" but he entirely fails to recognise the fact that this is mainly caused by the date of the metropolitan Show being far too early for the northern men, who very naturally see no reason for subscribing as long as it remains impossible for them to compete at the Exhibition of the Society. Those who have been on the Committee for any length of time cannot fail to remember how strenuously Mr. Hall used to urge that it was impossible for the northerners to be ready, and it is an open secret that the loss of his support, both of the Society and of the Shows, has been caused by the persistent sticking to the late date. The same cause, I am informed, contributed largely to Mr. Whitwell's withdrawal. If Mr. Pemberton's motion were adopted, and so it made possible for the metropolitan Show to fall as late as July 9th once now and then, there would very speedily be no room for the question, "Where are the Northern Exhibitors?"

#### PROXY VOTING.

As this proposal seems to be beset with difficulties (though I certainly think these are more imaginary than real), may I suggest that when an important matter, such as the proposed alteration of date, or the like, arises, a *plébiscite* of the members should be taken by post, and action determined accordingly. Post cards are cheap, and if this course were adopted members who are hindered by distance from coming up to vote would feel that they still had some voice in the affairs of the Society, and their interest would be maintained and increased.

#### TEAS IN MIXED CLASSES.

Closely connected with the early date of the metropolitan Show, a grievance has arisen as to boxes containing nothing but Teas and Noisettes winning the prizes in the mixed classes. There is a provision in the rules that Teas and Noisettes shall have no especial favour shown them, and yet in three mixed classes at the last Crystal Palace Show boxes of Teas only were allowed to win, while if a solitary H.P. dared to show itself among the Teas and Noisettes the stand would be at once disqualified. What about "No especial favour" after that? Under ordinary circumstances perhaps there would not be much hardship, but Teas are always at their best a fortnight before the bulk of H.P.'s, and when the latter are further handicapped by such a date as July 1st, it gives the Tea men a great pull, and I certainly think there should be a provision that in the mixed classes not more than one-third of the required number of blooms should be Teas. Bearing in mind the large and increasing provision which is made in the schedule for Teas only, such a regulation seems to be a measure of the barest equity.—J. B.

#### MOSS.

It is a very doubtful point indeed whether in awarding prizes the dressing of a stand comes into the decision. Like "W. R. Raillem" (page 70), I cannot say that in judging the moss, or any substitute for the same, has ever caught my eye. Like the *tout ensemble* of the stand, it seems to me it can only come into competition when two stands are so absolutely equal that there is no saying which is the better. Even then, excepting when a cup is at stake, it would be far better to add first and second prizes together, divide, and award equal firsts. This, however, is matter of opinion, and as such alone do I give it. I was not fortunate enough to see the Peterborough grower's stand, but I have often thought that, given a good shade of green, that velvet would be the thing (my daughter, hearing this, says "plush"); but then, look at the expense. We cannot exhibit Roses without water, and every spot of water would show, for both velvet and "plush" would "set up their backs" at a drop.

For Chrysanthemums I have used green baize; that stands the wet, and I (but then it was my own child) did not think the baize by any means a bad substitute. Most of us have something to cover the boards. Mr. Molyneux, I think in his book on the Chrysanthemum, says they look better on the plain board than on anything else; but I am afraid that most of our Rose boards, like a school child's letter, would not "bear inspection" because pierced by different numbers of holes—any way, mine are! It has occurred to me that worsted or wool might be made useful in this direction. The method that strikes me is this—say twenty threads of worsted, an inch off another twenty, these crossed by other lines of twenties, either tied at every inch where they cross or knotted, then when thus firmly tied let half the threads be cut through and fluffed out. But to come to moss.

I recollect in my early days a lady saying to me something like "W. R. Raillem's" speech. "What beautiful moss yours is!" I certainly agreed with her; and to my mind if moss is the thing that sort appears to me the best. I always used to get it off the large coping Bath stones on the top of walls. This moss lies close to the stone, is not more than half an inch thick; may be got off with a blunt knife in large pieces where found, but is not very common. If dry and brown, I brought it home, plunged it into a bucket of water for twenty-four hours, then

squeezed it nearly dry and spread it out. In another day it would recover its lovely green colour and be fresh, though, of course, it is best in moist dripping seasons. It lies close on the boards, allows one to

FIG. 16.

push a tube through, and to my mind is the Al covering. It is a beautiful dark green when in condition. This I have afterwards laid on the tiles, and some of it has grown there. The moss on thatch is very different. It is very thick, sometimes 1½ inch, and does not lie evenly on the board. In some parts of Longleat Woods, at the roots of some of the trees, a beautiful kind of moss is found often; also growing amongst the grass on some of the banks. It is more like fronds of Fern, some of which are 4 inches long. I have seen this used often, but beautiful as the moss is by itself, it always appeared to me untidy as a covering; moreover, the colour is a greenish yellow, and rarely all the same shade. Some years ago, when moss was discussed, it was said by some exhibitors that the dampness of moss dulled the colour of the Roses. If this is true it is a serious objection to moss, and a dry substitute would be welcomed.

The moss I speak of as being found on the coping stones of walls, grows rapidly. For years I took off all I could find, with the exception of little stray pieces, yet in course of the winter the same spots would be covered again. It grows best where overshadowed by trees.—Y. B. A. Z.

#### RAISING SEEDLING CARNATIONS.

THE raising of seedling Carnations is one of the most fascinating pastimes the experimenter can engage in. It is fraught with hopes, fears, and disappointments, and frequently, to the severely practical man, apparently unjustifiable elations. There is a number of practical florists, and some amateurs, engaged in the raising of seedling Carnations with a view to their improvement, and there are many others who would take up this laudable undertaking if they knew just where to begin. It is for the latter class that this article is prepared.

It is interesting to know the origin of meritorious varieties, not for the purpose of repeating the experiment, for it is ten thousand chances to one that the results would be the same, for there are rarely or never two varieties that might be pronounced identical even from the same seed pod. But it is so much knowledge to our credit, and it may act as a guide for future operations. Though he who thinks he will electrify the floricultural world by his achievements after he has earned the pedigrees of the best sorts by heart may be disappointed, yet such is among the possibilities. A novice might effect a cross between two varieties without any idea as to what the effect would be, and the result might be greater than that of a person who has been experimenting with a definite object in view for years. This is where that element which is known as luck comes in. Yet there are very few, I venture to say, who have ever indulged in this mild form of excitement who would throw aside system, no matter how fortunate someone

FIG. 17.

else may have been in a haphazard way, and depend entirely upon luck. I believe in pedigrees, for by careful records, with close observation, we may note the influence of varieties as breeders; some may be much more potent than others.

In explanation of the illustrations, fig. 16 is a Carnation flower

showing the pistils prominently, which may be called the pistillate, seed or female parent, all of which are synonymous terms. Fig. 17 is a flower which shows the stamens conspicuously; these furnish the pollen with which to fertilise the pistillate flower. Generally speaking, a Carnation flower may be made either the pollen or the seed parent, as the operator may determine, though there are exceptions to this rule. I found this out some years ago when hunting among some flowers of the variety Duke of Orange for pollen, but not a grain could I find. On the other hand, I have operated upon varieties which did not produce perfect seeds.

In fig. 18 we find a representation of a flower ready to be operated upon. The petals have been carefully removed with the finger and thumb, part of the calyx has been cut away by a sharp pair of scissors, showing the ovary with the pistils standing out above.

Fig. 19 gives the stamens and pistils. The stamens are the more apparent, and shows the pistils before they have developed far enough to be fertilised.

Fig. 20 is similar to the last. On close examination it will be seen that some of the pollen cases have burst, thus freeing the meal-like pollen, which may be carried by a camel's-hair brush, to which it readily adheres, and applied as seen at fig. 21, where the operator is in the act of applying the pollen. Camel's-hair brushes may be obtained at a trifling cost. Where there is any choice it is best to select the darkest brushes, as the pollen grains are more readily seen on this material than when it is of a greyish colour, thus giving the practitioner a better idea what he is doing. In all our operations there is always a danger present and a possibility of self-fertilisation. To avert this it is better to remove all the petals and stamens at an early stage of the flower's development, before the stamens have had time to ripen its fructifying grains, thus destroying a possibility of frustrating our plans.

Fig. 22 gives an idea how the seed pod should look when it has advanced somewhat, although this cut is more to show the manner of keeping a record of the cross made. Some prefer to mark the tag only with a number and to keep in a note book the full particulars, but if the note book happens to get lost the numbers are very little value. A full record on the tag is best, I think; then there is little or no danger of losing it. It is cheaper to buy the little tags than to make them. They are sold with strings already attached, which renders them easily adjusted, and gives the whole operation a neat and workmanlike appearance. In recording the cross, the name of the seed parent comes first. Whether it is correct to make a plus mark or a multiplication mark (×) I have not been able to determine.

FIG. 18.

We may multiply varieties without adding to their quality. Each one may make the mark which suits him best.—EDWIN LONSDALE (in "*The American Florist*.")

#### NEW ZEALAND GARDENS AND CLIMATE AT CHRISTMAS.

I HAVE recently received the enclosed newspaper cutting from a relative at Auckland, New Zealand, to whom I occasionally send your paper, which I take in regularly. I thought you might like to insert it as showing what a splendid climate our colonists there possess, and what a fine season they appear to have had this last summer of theirs, corresponding in time to our winter here.

I may mention that my relative takes a great interest in his garden, and last year he sent me in March, which I received in May, a box of freshly gathered Northern Spy Apples of his own growing, which reached me in excellent condition, coming by steamer in one of the cool chambers. They were splendid specimens both in appearance and flavour, and averaged a weight of three-quarters of a pound each.—CHAS. H. PAGE, *Dulwich House, Cardiff*.

We insert with pleasure the extract from the New Zealand paper, dated December 23rd, 1892, as sent to us by Colonel Page; it is as follows:—

"The splendid weather we are having has afforded ample opportunity for destroying weeds and placing the whole of the garden and grounds

in neat and trim condition, in keeping with the holiday season we are now about to celebrate, and in giving the operator leisure to thoroughly enjoy the result of his or her past labours. There should not be a vacant or unplanted spot in either the flower or kitchen gardens. Both should now be replete with flowers and vegetables of every description. Happily, with us in New Zealand, the festive season comes when this can be accomplished, as the various departments may now be stocked with almost everything that is suitable for our climate. At this Christmas Nature is more beneficent than usual, bestowing her gifts with such wonderful profusion that even the most callous amongst us cannot but be struck with admiration at the endless variety of beautiful trees, plants, flowers, and fruits that everywhere abound, and by the verdure of the grass and other natural products that clothe and adorn our beautiful landscape. The frequent genial rains and splendid growing weather experienced throughout the spring, and up to the present time, have imparted an unusual health and vigour to plant life, and aided in maintaining that freshness of foliage and appearance that everywhere meets the eye and gladdens the senses, adding also further to the charms and pleasures of the open air.

"Visitors to this remote region of the globe carry away lasting expressions of our genial climate and picturesque surroundings. Happy, indeed, should be our lot, living in this fair land of sunshine and flowers, and in a climate free from the extremes of heat and cold, and where our homes may be made bright and cheerful with the bountiful

FIG. 19.

FIG. 20.

products of the land. Here in our island home rich and poor alike can revel in sunshine, and pass a pleasant time with but comparatively little outlay. How different to the Christmas that many of us have been accustomed to where hard cold winter, with its frost and snow, was the natural harbinger, and where flowers and fruits could only be obtained by artificial means. Here our splendid climate and natural resources afford pleasures that are unobtainable in less favoured regions, and where the festive season takes place in the winter.

"Our Christmas Tree, the Pohutukawa, takes the place of Holly and Mistletoe, the natural emblems of this season in England. This magnificent tree may be seen growing along our coasts laden with the utmost profusion of conspicuous dark red blossoms, standing out in bold relief from the endless variety of the surroundings. Truly, ours is a land of fruit and flowers. Both may now be had in abundance. In fact, nothing is wanting as far as Nature is concerned in adding to the pleasures of the present season. In addition to our own temperate fruits, tropical fruits, such as Bananas, Oranges, Pine Apples, Mangoes, and other dainties, the products of the adjacent islands, are within the easy reach of all, a privilege that can be enjoyed to the fullest extent in this southern hemisphere. The endless variety of flowers that now adorn our garden and grounds not only add to the outdoor enjoyment, but are also useful for gathering to beautify and enliven the dwelling. There are now such a host of beautiful varieties in flower that it is needless to attempt to enumerate even a small number. The season has been one of the most favourable for the growth of the different garden products that has been experienced for many years."

The Christmas scene described by the writer is, we have reason to know, described with accuracy. New Zealand is a magnificent colony with in most parts a rich soil and delightful climate. A thirty years' resident refers to it as a "land of health and plenty, where all who are able and willing to work for a living will find a good one in the beautiful land." The Pohutukawa tree alluded to is a species of *Metrosideros*, laden with crimson bottle-brush flowers in November and December.

#### PRICES AND QUALITY OF APPLES—MANURE.

MR. KRUSE returns to the subject of the price and quality of Apples only to bring the same charge of irrelevancy against two other correspondents as he has brought against myself. In his first communication he wrote, "At the time Domino made about 1s. home, larger sorts made 2s. per bushel home for selected fruit. It is true that some of the others made sometimes during the season 6s. per bushel in Covent Garden, or about 4s. 9d. home, but this was very exceptional and not the rule." Why, in the face of these words, does he persist that to refer to other

varieties than Domino is to wander from the point at issue? Clearly and unmistakeably because it has been abundantly proved that notwithstanding his repeated laudatory remarks about his own fruit that of

FIG. 21.

other cultivators has fetched a better price in the market. Before superior returns were quoted against him he was prepared to refer to the prices brought by other varieties, but afterwards he discovered that they were a "side issue" and became anxious to retire from the "wordy controversy."

As I have forwarded documentary evidence in proof of the statements which I have made that what are "exceptional" prices in the case of Mr. Kruse's fruit are not so in another, and several other correspondents have come forward to support me, surely the wisest and most dignified course for him to pursue would be to take a broad and comprehensive view of the position, and cease these futile endeavours to find protection in a shelter which his own words have shattered. There is a great question at issue, one on which it is of the highest importance to have an accurate reply. I did not cross swords with your correspondent on this matter without preliminary deliberation, for as an experienced and observant cultivator his opinions were entitled to a respect which I do not claim as an equal due for myself; but facts in my possession proving indisputably that there was another side in addition to the one which he took up, I set myself to present it clearly and correctly before your readers. Whether I have succeeded or not is for them to judge. I have not replied in kind to charges of "heat" and "superficial knowledge," partly because I have had a long enough experience of the ways of the world to be able to smile at these things as matters of course, and partly because I have no sympathy with endeavours to degrade a great public question to the level of a personal controversy.

I know not from what point of view readers in general view this question of the profit of fruit growing, but it must seem to many to have issues too momentous to rest upon personalities. There is work to be found for thousands of willing hands and food to provide for our teeming millions. Can English soil provide both by corn growing? No, and we look to fruit as an adjunctive aid to cultivators. Only thoughtless and irresponsible agitators will proclaim it a mine of wealth, but if a fair return can be realised it will be of great benefit to the country. Working from this standpoint it has been my endeavour to show what can be done with energy and enterprise combined with cultural skill. Neither yards of figures nor clumsy methods will avail. The former tempt, but they do not produce. The latter may have some

FIG. 22.

results, but they will be unsatisfactory and profitless. With care and judgment waste acres may be made productive, and, as at Swanley, where the skill and courage of Mr. Henry Cannell have set so valuable an example, the land that has fed the few becomes capable of feeding the many.

A few words as to the manures. Mr. Kruse says that his statements on the subject are facts. If he will turn to his article in the *Journal* of December 15th he will find that he advanced £500 a year as his annual

expenditure on manure, not as a fact but as an "estimate," and estimates are made to be criticised. It is extraordinary that he should meet my request for particulars about what he is doing now with manures by referring me to what someone else did in another district upwards of twenty years ago. But to oblige him I have turned up the articles referred to and found, as I expected, that for practical purposes there is absolutely no connection between the two cases. Your correspondent has estimated that he spends £12 10s. per acre annually on manure for land, "all of which is under fruit cultivation." What comparison is there between this and £20 per acre expended on land under market vegetables? Mr. Kruse appears to rely upon mulching, but how under this practice he utilises the enormous quantity indicated by his "estimate" of £500 a year for 40 acres of land I fail to see, and I happen to know that many others share my difficulty.

I observe that although Mr. Kruse advances 10s. per ton as the cost of stable manure, he is careful to avoid saying that it costs this to him. The price appears to represent what someone else has paid elsewhere. Further, he adds that the cost of labour is to be added to that of the material, although when he first wrote he spoke of his "manure bill" alone. When a man uses this term he is generally understood to mean the cost of manure to his premises, not the application of it as well. This generally comes in the wages account, and in his previous letter Mr. Kruse made a separate charge for this of another £500 a year. From this it will be seen that he declines to supply the only information which would be of practical use to readers. The grounds for refusal are by no means satisfactory. He bases them on the assumption that the information is sought with a spirit of finding fault. If, however, his estimates are accurate and his methods sound, surely the best plan of bringing carping critics to grief is to supply the explanations asked for, not to take refuge in silence. That which is right and good will stand the test of fault-finding. However, he distinctly refuses particulars, and there, I suppose, the matter ends. The salesman's returns, giving prices home to the grower of Apples, that I have sent to the Editor show clearly that Mr. Kruse is less fortunate than some others in his sales, and those returns, which no one can question or explain away, are ample justification for what I have said on this subject.—W. P. W.

**EVENTS OF THE WEEK.**—As stated below, the Committees of the Royal Horticultural Society will meet at the Drill Hall, James Street, on Tuesday, February 14th, and the annual general meeting of the Society will be held at 3 P.M. The Committee of the National Rose Society also meet at the Hotel Windsor on Tuesday afternoon, and the annual dinner of the Horticultural Club takes place in the evening at the same hotel.

— **THE WEATHER IN LONDON.**—The weather in the metropolis has been of a variable character during the past few days. Sunday proved cold and frosty with local fogs, freezing hard at night. On Monday morning a thick fog prevailed in the north of London, but it cleared during the day and became milder at night. Tuesday was fine, mild, and springlike, similar weather prevailing at the time of going to press.

— **WEATHER IN THE NORTH.**—The first week of February has been on the whole mild for the season, the days generally dull with occasional showers and a touch of frost on two mornings. Sunday was for some hours almost spring-like in temperature and brightness, but became cold and dull in the afternoon. Snowdrops are in bloom, and Crocuses are showing above ground. Roses seem terribly cut up by the frost, not a few killed outright.—B. D., *S. Perthshire*.

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting of the Society will be held on Tuesday, February 14th, at the Drill Hall, James Street, Westminster. As the annual general meeting will be held the same day at 3 P.M. at the Society's offices, 117, Victoria Street, it is expected that there will be an unusually large attendance of Fellows to hear the report of the past year.

— **FRUIT CULTURE IN THE SCILLY ISLES.**—A western contemporary states that during the next few months an enterprising syndicate of fruit growers will lease the entire group of the Scilly Isles from the proprietor, and English-grown Oranges may in the near future be competing with Valencias in Covent Garden Market. No snow has fallen at Scilly since the spring of 1890.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—The members of this Association held their second annual general meeting at the Memorial Hall, Farringdon Street, on Tuesday, February 7th, under the presidency of Mr. T. W. Sanders. The report of the Committee showed that much good had been accomplished by the Association, and that there were now upwards of 400 members, with several affiliated societies. According to the financial statement, too, there is a satisfactory balance in hand, and this, with an excellent syllabus for the ensuing year, augurs well for the future success of the Association. A Fellowship of the Association was conferred on Mr. G. McLeod of Chingford for valuable services rendered, this being the first distinction of its kind bestowed on any member since the inauguration of the institution.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of this Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 15th instant, at 7 P.M., the following papers will be read:—"Report on the Phenological Observations for 1892," by Edward Mawley, F.R.Met.Soc.; "Relation Between the Duration of Sunshine, the Amount of Cloud, and the Height of the Barometer," by William Ellis, F.R.A.S.; "Winter Temperatures on Mountain Summits," by W. Piffe Brown.

— **"KARRI" WOOD FOR PAVEMENTS.**—At a recent meeting of the Royal Botanic Society of London, it was announced that the donations included specimens of the Karri wood, a hard reddish-coloured timber produced by one of the Australian Gum trees, *Eucalyptus diversicolor*, and now imported to a large extent for paving roads. The Secretary stated that, though Australia abounded in useful timbers, few of them had been utilised to any extent in England.

— **VALUE OF A CHERRY TREE.**—"A question as to the value of a Cherry tree," says the *Kölnische Zeitung*, "has just been decided at Niederlahnstein, in Germany. The ground whereon this Cherry tree stands is required for the widening of a railway station at that place. The owner of a tree put in a claim for £180, which he said was the amount he obtained yearly from the fruit the tree yielded. After some spirited contention on both sides the owner somewhat reluctantly consented to accept £120." Is not this a "chestnut?"

— **TOBACCO CULTURE IN AUSTRALIA.**—It is rather surprising that Tobacco has been so little cultivated in Australia. The *Agricultural Gazette* of New South Wales has taken up the matter, and in a recent number devotes to it a comparatively long and interesting paper. The writer of the article thinks that the climate of New South Wales is admirably suited to the growth of Tobacco, and hopes that a sufficient quantity of it may hereafter be produced not only to satisfy local demands, but to open up a large and lucrative export trade.

— **A CARNATION NUMBER.**—Our excellent transatlantic contemporary, *The American Florist*, keeps well to the front. A few weeks since we referred to its special Chrysanthemum issue, and now we have a Carnation number before us. It is replete with pithily written useful information about these beautiful flowers. The illustrations, moreover, are plentiful and admirably executed. The portion of an article on raising seedling Carnations, which we reproduce with the accompanying illustrations elsewhere in the present issue, will doubtless be appreciated by our readers.

— **AMALGAMATED HORTICULTURAL SOCIETY FOR GRAVESEND.**—At the Town Hall, Gravesend, a meeting was recently held to inaugurate the newly consolidated Horticultural Society, which was formed upon the dissolving, by mutual agreement, of the three old Associations, the North Kent Chrysanthemum, the Gravesend Horticultural Improvement, and the Gravesend and Northfleet Horticultural. The Mayor (Mr. G. M. Arnold) presided, and there was a large attendance. The amalgamation will be known as the Gravesend, Northfleet, and District Horticultural Society.

— **CORBRIDGE AND DISTRICT GARDENERS' SOCIETY.**—A meeting of this Society was held in the Town Hall on Monday, January 23rd, Mr. Charlton, Farnley Grange, presiding. Mr. W. J. Watson, Corbridge, read a paper entitled, "My Experiences as an Exhibitor of Spring Flowers." Having been a successful exhibitor for many years at Newcastle and other Shows, Mr. Watson's account of the various exhibitions he has attended was most interesting. He gave some good information on bulb growing, which was much appreciated by all present. Mr. Bell proposed a vote of thanks to Mr. Watson for his excellent paper, also to the Chairman who so ably presided.

— **THE SALE OF FRUIT.**—It is stated that Sir William Hart Dyke intends to introduce a bill into the House of Commons relative to the regulation of the sale of foreign and colonial fruits.

— **LONDON COUNTY COUNCIL APPOINTMENT.**—We are informed that Mr. G. Gensel, Assistant in Kensington Gardens and Hyde Park, has been appointed landscape draughtsman in the Parks Department of the London County Council.

— **BOTANIC GARDEN APPOINTMENT.**—Mr. Robert Harrow, formerly of Cambridge and late of Kew, has been appointed recently from the latter establishment to the foremanship of the houses in the Royal Botanic Garden at Edinburgh.

— **THE JUDAS TREE.**—As yet no gardener has, it appears, answered my query (page 49) about the presumed poisonous quality of the honey of the Judas Tree. Perhaps it is a statement that seems too absurd to call for a reply, especially as it comes from across the Atlantic.—J. R. S. CLIFFORD.

— **RAINFALL IN SUSSEX.**—The total rainfall at Abbot's Leigh, Haywards Heath, Sussex, was 2.04 inches, being 0.20 inch below the average of mid-Sussex. The heaviest fall was 0.67 inch on the 9th. Rain fell on fourteen days. The maximum temperature was 51° on the 31st, the minimum 15° on the 4th and 5th. Mean maximum 39.1°, mean minimum 30°. Mean temperature 34.5°; slightly below the average.—R. I.

— **THE WEATHER LAST MONTH.**—January was a changeable month with very little sunshine; we had nine bright days, one of which was clear. The wind was in a westerly direction for twenty-one days. Barometer, highest 30.39 at 9 P.M. on the 4th; lowest, 29.57 at 9 P.M. on 16th. Total rainfall 1.45 inches, which fell on twenty days; the greatest daily fall being 0.28 inch on the 26th. The total is 0.48 inch below the average for the month. Highest shade temperature, 52° on 30th and 31st; lowest, 5° on the 5th; lowest on grass, 3° on the 5th. Mean of daily maximum, 40.03°; mean of daily minimum, 28.77°. Mean temperature of the month, 34.30°. The garden spring ran 24 gallons per minute on the 31st.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS.**—January, 1893.—Mean temperature of the month, 35.5°; maximum on the 31st, 54.7°; minimum on the 5th, 8.5°. Maximum in the sun on the 31st, 93.4°; minimum on grass on the 5th, 6.1°. Mean temperature of air at 9 A.M., 34.7°; mean temperature of the soil 1 foot deep, 34.3°. Nights below 32°, in shade seventeen, on the grass twenty-five. Total duration of sunshine thirty-four hours, or 14 per cent. of possible duration; we had sixteen sunless days. Total rainfall, 1.37 inches; rain fell on seventeen days. Average velocity of wind, 9.8 miles per hour. Velocity exceeded 400 miles on three days, and fell short of 100 miles on two days. Approximate averages for January:—Mean temperature, 37.1°; sunshine, 35; rainfall, 1.69. The first week was very cold, after which it turned rather milder; but the thaw was a slow one, and the frost was not out of the ground until the 22nd. The rest of the month was mild. Mean temperature about 1° higher than the last two Januarys. Snow on the ground for the first twelve days.—J. MALLENDER.

— **LILY OF THE VALLEY.**—Having been rather successful with the culture of Lily of the Valley this season, a few details of the treatment we have given them may perhaps be interesting to readers of the *Journal of Horticulture*. In the first place it is absolutely necessary to obtain good crowns. Having secured these, place them in 5-inch pots, using a mixture of loam, leaf mould, or some old peat. From fifteen to eighteen crowns will be found sufficient for one pot. Great care must be taken to ram the soil firm. After potting they should be stood outside, and the crowns well exposed to the frost for a few weeks. Introduce as required, and stand them in shallow zinc tanks over the pipes in the forcing house, keeping them dark, and taking care to maintain a moist atmosphere. A little moss placed over the crowns will assist in keeping the soil moist, which is most essential. After they have started and began to show the flower spikes remove to a close frame inside the forcing house, gradually introducing them to the light. When the flower spikes are well advanced they may be brought out and gradually hardened for the purposes they are required. We have had them in flower twenty-one days from the time they were taken in, with strong spikes, making a grand display under the above treatment.—BRAMLEY.

— **MEALY BUG ON VINES.**—The following is one of the best mixtures I have seen used to remove mealy bug from Vines:—3 pints of sweet oil to 1 pint of petroleum, thoroughly mixed, and put on with a brush.—GEORGE TABER, *Rivenhall, Essex.*

— **GOLDEN WEDDING OF DR. AND MRS. PATTERSON.**—Many readers will join us in our congratulations to Dr. and Mrs. Patterson, of Bridge of Allan, who celebrated their golden wedding on the 25th ult.

— **GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—We have great pleasure in announcing that Baron Schröder has kindly consented to preside at the fifty-fourth annual Festival Dinner at the Hôtel Métropole, on the 22nd of June next, in aid of the funds of the above Institution.

— **ENGLISH GRAPES IN NEW YORK.**—A few weeks since it was announced that English Black Hamburg Grapes were selling freely in America at remunerative prices. Now, according to the "Garden and Forest," Gros Colman Grapes imported from England are realising 8s. per lb. in New York.

— **REPORT OF WEATHER DURING JANUARY, 1893.**—The past month has again shown us how very fickle is our climate. January began with exceptional severe frost; on the morning of the 5th 25° were registered on the ground, whilst the month ended with weather of a very mild character. Rain and snow fell upon seventeen days during the month. Maximum in any twenty-four hours was 0.39 on the 28th; minimum in any twenty-four hours was 0.01 on the 24th. Total during the whole month, 1.67, against 0.64 of 1892.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

— **AGAVE RIGIDA.**—At the meeting of the Royal Botanic Society on Saturday, 28th ult., Mr. Granville R. Ryder in the chair, there was shown from the Society's Gardens a plant of the Sisal Hemp, *Agave rigida*, now extensively grown in the Bahamas and Central America for its fibre. The Secretary said that until lately, with the exception of two or three fibre plants, as Hemp and Cotton, commerce depended upon wild plants for its supplies; but so great was the demand now for fibres for papermaking and other uses, that it had been found necessary to grow them specially. He believed that the plants producing the Bowstring Hemps, or Sanseveiras, would be found also well adapted, owing to their manner of growth from rhizomes spreading along the ground, making them easy of propagation and cultivation.

— **MARGARET CARNATIONS.**—Calling to-day at the Sparkhill Nurseries I found Mr. Herbert cutting down his seedling Margaret Carnations preparatory to their breaking for cuttings, and I enclose you two very small lateral blooms of one of them to give you an idea of the strong Clove perfume they have. They are from a plant which has been in bloom since August from seed sown in February last. You will see at once that even this variety is a great improvement on the ordinary Margaret Pink, and is, as I have said in previous communications through the *Journal*, the result of a cross between a Margaret Pink and a crimson bizarre Carnation, Robert Houlgrave.—W. DEAN, *Birmingham.* [The blooms sent show a great advance on any Margaret Pinks we have seen. The colour is deep crimson, petals broad, only slightly serrated, and the perfume delicious; an acquisition worthy of a good name.]

— **NARCISSI FROM THE SCILLY ISLES.**—Three years ago the farmers in Scilly were beginning to appreciate the necessity for getting their Narcissus flowers on the market as early in the year as possible, and to endeavour to secure that end by forcing. The first attempts were rude and experimental; but the farmers have been apt pupils, and the forcing process has now developed into something like a fine art. In the old days the half-opened blooms were plucked, and then plunged into hot water, or into the family oven, to open. The next development was the introduction of tanks, where the flowers were forced by steam. Now, however, these clumsy contrivances have given place to forcing houses of glass. The bulbs are placed in boxes, and at a certain stage are put into the forcing house, where, under the influence of a constant and carefully graduated heat, the buds come up and open with surprising quickness. Everyone who can afford it builds a forcing house, and the ambition of those who have one is to speculate in more. The bulbs do not retain their strength under this treatment, and are usually unfit for use a second year; but a few thousand bulbs, more or less, are of little consequence nowadays. The present season has opened well, and large consignments are being despatched every week to the London and midland markets.

— MANURES FOR ORCHARDS.—Most of the successful attempts to renovate old Apple orchards have required large amounts both of mineral and stable manures. It is likely that the latter was mainly efficient in keeping the soil open and supplied with carbonic acid gas, and thus preventing the mineral manure becoming insoluble. When vegetable matter is deficient the tree roots cannot get the benefit of the mineral fertility that the soil contains. Old orchards often suffer thus, and are made productive again by supplies of stable manure that has itself very little mineral matter, but makes available what the soil already contains. There need be no fear of making the soil around large trees in full bearing too rich. If young orchard trees are fertilised or cultivated too highly they will run to wood; but in older trees this extra supply of nutriment will, if the trees be properly pruned, be turned to the production of a richer and better flavoured fruit than the larger specimens which very young trees occasionally produce.—(*American Cultivator*.)

— UNCERTAINTY OF BROCCOLI.—It is some years now since I last grew Snow's Winter White Broccoli. The heads were small, very uneven in form, and they used to "turn in" generally two months after the stated time. I tried seed from several sources, but all turned out the same. Some may say the seed was sown at the wrong time or the cultivation was wrong. I generally sow the seed of all Broccoli from the middle to the end of March, but in the case of Snow's a part of it was sown a month later as well, the result was just the same. So I gave it up the moment I found a superior substitute in Sutton's Mammoth White. For our land we cannot find another sort equal to this for giving us clear white good sized heads during January and February. Even this variety shows how variable the "turning in" of varieties are in different seasons. Michaelmas White, which is one of our best early Broccolis, was fit for use fully six weeks before its proper time, and the same might be said of some other sorts. Therefore it is not wise to discard a variety for one year's trial, but in my case I grew "Snow's" at least eight seasons and never had really good results from it.—E. M.

— WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—A meeting of the above Society was held in the Mechanics' Institute, Mr. T. Davies, Wavertree Nursery, presiding. The prize essay on "Mushroom Culture," by Mr. Wm. Disley, was read, and provoked considerable discussion, so much that the paper by Mr. R. G. Waterman on "Soils and their Treatment," had to be postponed for some future date. At the close of the meeting an interesting event took place, viz., the presentation to Mr. H. Corlett, The Gardens, Woolton Wood, of the beautiful silver medal given by the proprietor of the *Journal of Horticulture* for the best paper on the "Principles of Heating." In presenting it the Chairman made a most suitable speech for the occasion, which was replied to by the recipient of the medal. In submitting their fourth annual report the Committee had to record a successful year's work. All the papers read have been of a practical description, that by E. G. Baillie, Esq., of Chester on "Vegetarianism" giving unqualified pleasure. The lectures on "The Geographical Distribution of Plants," by R. J. Harvey Gibson, Esq., M.A., proved most successful, giving as they did useful and valuable information to the gardener and all lovers of horticulture. Dr. T. L. Bailey's course on "The Chemistry of Soils and Manures" would undoubtedly prove of considerable benefit to the cultivator, and it is to be hoped that the subject may be continued next session.

— WHAT IS THE TRUE SHAMROCK?—Most Irishmen are probably of opinion that they can answer the question correctly, but unfortunately they do not all give the same reply. Mr. Nathaniel Colgan, who has been investigating the subject, collected thirteen specimens from the following eleven counties—Derry, Antrim, Armagh, Mayo, Clare, Cork, Wexford, Wicklow, Carlow, Queen's County, and Roscommon. Shamrocks were thus secured from northern, southern, eastern, western, and central Ireland, Mr. Colgan's correspondents in the various counties taking pains to have each sample selected by a native of experience who professed to know the genuine plant. All the specimens were planted and carefully labelled with their places of origin, and flowering within some two months later gave the following results. Eight of the specimens turned out to be *Trifolium minus* of Smith, and the remaining five *Trifolium repens* of Linnæus. Cork, Derry, Wicklow, Queen's County, Clare, and Wexford declared for *Trifolium minus*; Mayo, Antrim, and Roscommon for *Trifolium repens*; and Armagh and Carlow, each of which had sent two specimens, were divided on the question, one district in each county giving *T. repens*, while the other gave *T. minus*. These results are set forth by Mr. Colgan in an interesting paper in the first volume of the "Irish Naturalist."

Elsewhere in the same volume Mr. R. L. Praeger suggests that authentic specimens of Shamrock should be obtained from every county in Ireland, and he adds that he has no doubt Mr. F. W. Moore would gladly grow them at Glasnevin Gardens, if Mr. Colgan did not care to undertake so large an order. Mr. Praeger notes that in his own district, North Down, *Trifolium minus* is always regarded as the true Shamrock, but that a luxuriant specimen, or one in flower, is generally discarded as an impostor.—(*Nature*.)

— BROCCOLI.—It would be very interesting to learn what has been general experience this winter in relation to the effect of the recent severe weather upon Broccoli plants grown in ordinary loose soil, and in that which has not been dug for two or three years, and is in consequence very firm if not hard. I observed in several gardens last summer that old Strawberry beds from which the plants had been cleared off, but had not been dug or otherwise disturbed, had been planted with Broccoli plants with the avowed object of having them of a very hardy nature. I should now very much like to know whether, as complaints are made already of the harm done by the recent frost, the plants on such hard soils are uninjured. If they have come out of the hard weather in much better condition than have plants on soft summer-dug ground, then much is gained. If they have not, then nothing would seem to be gained. Then it would be interesting to learn whether early or late kinds have so far wintered best. It may be assumed that the early section, if not actually tenderer than are the late sorts, is at least in a far more active condition of growth in midwinter, hence much more likely for that reason to suffer from severe frost. Without doubt Broccolis have suffered greatly during the past severe winters, and the suggestion of "W. S." (page 70) that all the early section be lifted and laid in either houses or pits is one that merits every consideration. It is useless to plant in the summer if breadths be left, only to be killed by frosts in the winter.—INQUIRER.

— TROPICAL VEGETATION.—An American professor, Mr. D. H. Campbell, gives in the *Botanical Gazette* a very vivid description of the flora of the Hawaiian Islands. The first thing which struck him on reaching Honolulu was the brilliant colouring of the tropical vegetation. All possible tints and shades and varieties of green were seen in the bay and on the mountain slopes—"a real symphony in green." Palms are, of course, the most prominent feature of the landscape. The Royal Palm, "with its smooth columnar trunk, looking as if it had been turned, encircled with regular ring-shaped leaf-scars, and its crown of plummy green leaves," is the grandest of all. Then come the Betel Palm, which yields the Areca Nut and the strongly perfumed cachou; the Wine Palm, the sweet sap of which gives wine after fermentation; the elegant Cocoa Palm, the Sugar Palm, and a great variety of Fan Palms. Another characteristic feature is the great number of leguminous trees. In our climate we chiefly know herbs and some vegetables belonging to this tribe, or a few shrubs (the Furze and the Broom), and very few trees (like the Acacia tree and the Judas tree), but in Honolulu leguminous trees are plentiful, and beautiful too. In the whole vegetable kingdom, we are told, there is no more splendid plant than the *Poinciana regia*, one of this tribe: "A spreading flat-topped tree, perhaps 30 feet high, with feathery green foliage and immense clusters of big, flaming scarlet flowers which almost hide the leaves, so that the tree looks like an immense bouquet." Another tree of the same family droops great bunches of golden yellow flowers and cylindrical pods 3 to 4 feet long, and close by it stands the graceful Algaroba, with fine feathery leaves and sweetish yellow pods of which animals are fond. Mingled with these are many species of Musa, or Banana plants, and a luxurious variety of showy flowering shrubs.

#### FUNCTIONS OF VINE LEAVES.

I HAVE no intention of reopening this discussion, because enough has been advanced on both sides to enable the numerous readers of the *Journal* to form a definite opinion on the subject; and even if additional arguments on my part were required they are in perfect readiness at 171, Fleet Street.

Nor do I intend to cavil with Mr. Iggulden for his extremely acute assumption that Mr. W. Baidney's well-reasoned contribution (page 525, last vol.) can be considered to have wholly supported him. What I want to draw attention to is the following remarkable sentence on page 89:—"There is no sense whatever in permitting Vines to expend their superfluous energies in the formation of foliage or wood that only interferes with their other functions." I do not remember having seen such a practice advocated at any time, certainly I have never advanced it; but I have repeatedly advocated, and still believe in, the value of practising extension and freedom of growth as a means of creating and sustaining vigour, fruitfulness, and permanent health. In this there is sound sense and logical reason.—H. DENKIN.

## CANKER IN FRUIT TREES.

(Continued from page 99.)

THE engravings fig. 23, *A* to *I*, are elucidatory of the article on this subject on page 27. In *A* is represented canker as a disease of fungoid origin, and not produced by any predisposing cause, or only indirectly by defects of cultural requirements or composition of the soil. The wounds are occupied in such cases around their circumference, or some part of it, by the mycelial threads or spawn of the fungus, *Nectria ditissima*, are swollen, fissured and scaly, and have an unsightly appearance. One such tree in a garden or orchard is sufficient to infect a parish, for the spores of the fungus are thrown off in countless

year nor in two or more, but the tree affected dies "hard," and as speedily recovers when "managed," which clearly indicates gangrene due to ill-nutrition. This cankerous affection is common in orchard trees which are so thickly branched and poverty stricken as to produce fruit little larger and almost as sour as crabs. A few doses of Mr. Tonks' mixture, 12 lbs. dissolved bones, 10 lbs. of powdered saltpetre, 4 lbs. of common salt, 2 lbs. of Epsom salts, 1 lb. of ground green vitriol, and 8 lbs. of ground gypsum, mixed, and applied at the rate of  $\frac{1}{4}$  lb. per square yard over the whole extent of soil within reach of the roots early in spring, repeating when the fruit is formed, would make such cankerous trees assume a different garb, and the wounds instead of gaping wide to receive every foul infection would soon be closed by new bark, an

FIG. 23.—APPLE TREES INFESTED WITH CANKER.

numbers, and they germinate under favouring climatic conditions. If the spores effect a lodgment on an Apple or Pear tree, and the bark is defective, it pushes its germinal tube into the inner bark and causes the destruction of the small twig (if such be assailed) in the year of attack, or in a larger branch produces a considerable excrescence and enlargement of the wound. Its cure is indicated in the figures *C*, *D* and *F*.

In *B* is seen a different kind of wound, not caused or occupied by fungal growths, but those caused by bruises, inimical climatic conditions, the burrowings of larvæ, and defects of soil—its staple, water-logged, or its composition. The wounds are shown in their healing state—the defects pointed out on page 28 having been rectified and the tree nourished, so that instead of having the bark round the wounds somewhat ragged, fissured, and scaly, as in *H*, they are in process of being covered over with clean healthy bark, as shown in *I*, otherwise this dry gangrene has some resemblance to canker caused by fungus. It, however, never becomes more than warted around the circumference of the wound, seldom is marked by excrescences larger than those produced by American blight or woolly aphis, and it does not kill small twigs in a

instance of which is shown in the white rings around those in the tree *B*. All this form of canker wants is "management."

The following are the particulars referring to the illustrations:—Apple tree (*A*) with canker caused by fungus (*Nectria ditissima*), and Apple tree (*B*) without fungal growths in the cankerous wounds. "*A*" tree references—*a*, canker caused by fungus in the stem; *b*, canker killing small branch in the year of attack; *c*, branch a year after being killed by the fungus; *d*, branch not entirely girdled; *e*, unattacked branches. "*B*" tree references—*f*, cankerous wounds (due to dry gangrene) on stem; *g*, wounds on the branches—all without fungus. Wound references—*C*, canker wound before cutting out the fungus; *D*, wound after the canker fungus (mycelial threads) has been cut out; *E*, result of imperfect operation, the fungus being left in the tree; *F*, successful operation, the fungal growths being excised, and new bark forming over the wound; *G*, fungus established, canker well developed—*i.e.*, *C*, two years later; *H*, wound without fungus growing in the inner bark around it; *I*, wound without fungus healing over. *Bar*, point of heading. *A*, a fungus-infested tree for regrafting.

Reverting to Mr. Kruse's case, an analysis of the soil is given

(page 564, last vol.), its management as regards manure clearly set forth, and the results in the health (and that means profitable production) of the fruit trees well defined. What more does anyone want to know? Everyone undertaking to grow fruit for profit should know what the land—the raw material out of which fruit is intended to be manufactured—contains. If the analysis is satisfactory, then we must look to the mechanical nature of the soil. If there is a plough pan or a pan within 2 feet of the surface that land will not grow Apples, Cherries, and Pears on free stocks satisfactorily; but “Plums, Gooseberries, and Black and Red Currants do well,” because they are surface rooting, and have many more fibres than Apples, Cherries, and Pears on free stocks, which to obtain the food their massive heads require must have a soil their roots can penetrate freely and deeply. A soil with a pan within 2 feet of the surface will need trenching and the bottom loosened, and drains will be necessary. These things are generally neglected, and the outcry is the trees canker and gum when they should be coming to full profit. Apples on Paradise, Cherries on Mahaleb, Pears on Quince, or double-grafted (with Plums, Gooseberries, and Currants) should only be attempted on such soil, for it is not naturally fitted for any other.

Draining does much to correct the evils of a pan, if the drains are deep enough to draw the water away, and let the sun, air, and rain into the soil and through the pan. Clays are the same; all soils may be made to grow anything the climate is fitted to produce, but the cultivator must decide whether it will pay or not. If the soil is naturally of a porous nature, but retentive enough for the due conservation of moisture and the economy of manures, 3 or more feet deep, and not below that surcharged with water, but naturally well drained, yet not excessively so, that will cost next to nothing in preparation, and it will give the best returns for the cultures, whatever they may be.—G. ABBEY.

(To be continued.)

## DISCUSSION ON POTATOES.

### QUALITY IN POTATOES.

WHAT a pity it is that Magnum Bonum is not of better flavour. It would be difficult to obtain a Potato equal to this for cropping, withstanding disease, and keeping plump and fresh over so long a season. Grown here, in our strong land, Magnum Bonum is almost devoid of that nutty flavour so much appreciated. Windsor Castle will, in my opinion, supersede this old favourite when it becomes better known. One hears much about The Bruce and the Dunbar Magnum Bonums, as well as Dunbar Regents. I presume, though, that these two varieties are simply grown at Dunbar, and differ in no other way from the ordinary strain. If tubers were sent from Cornwall to Dunbar, and grown there, they would, I suppose, be called by that name also; hence a confusion of names takes place. Many persons in this neighbourhood who grow Potatoes for market, some on lighter soils than this, have tried The Bruce, which is, I suppose, a form of Magnum Bonum, but it does not meet with much favour.

One of the best flavoured Potatoes that I have tasted was the old Scotch Rocks. Two points they possessed which were not favourable to the retention of this sort—deep eyes and yellow flesh. Many ladies, I find, think far more about the appearance of the Potatoes than their flavour; therefore, if a variety is mealy and white, it is considered superior to one with a tinge of yellow in it. Before coming south I used to buy Potatoes in the Liverpool market direct from the ship. They were of German growth I believe, of kidney shape, and most excellent in quality and appearance; 7s. 6d. was the price paid per bushel, which is slightly different to that charged in these days, when quantities can be bought for 1s. 3d. per bushel.—E. MOLYNEUX, *Swanmore Park, Bishops Waltham.*

### STORING POTATO SETS.

A GOOD deal of the success or failure of a Potato crop depends on the method of selecting and storing the sets. In too many cases we see the sets taken in the spring from a pit where they have been kept all the winter, covered with long weakly growths which have to be rubbed off before they can be planted. That the growth of the plant must be weakened by the loss of energy in the set is apparent. The best time to select the sets is when the crop is being harvested, and in my opinion those that give the best returns are undersized tubers of good shape, which can be planted whole. After being well dried by exposure to sun and wind they should be taken to a cold structure where frost can be excluded during winter, and spread out thinly. When a spell of bad weather occurs and outside work is at a standstill they may be examined, all showing signs of disease being taken out, and the rest packed closely together on shelves.

To facilitate work in spring it is a good plan to have shallow boxes made for the sets, so that being portable they can be taken to where the planting is being proceeded with. These boxes can be made to fit one above another, thus economising space by having square pieces of wood 8 inches high nailed to the corners, on the top of which another box can rest. Treated thus the sets are bristling with sturdy young growths at planting time, and they can be kept from making undue growth till well into the spring. I think late planting for main crops is advisable, as the soil being in better condition, and the weather warmer, they start unchecked, reducing the chances of blanks to a minimum.—O. C.

### WINDSOR, ETON AND DISTRICT CHRYSANTHEMUM SOCIETY.

WE are informed that the Committee of the above Society have fixed the date of their second annual Exhibition, to be held at the Albert Institute, Windsor, for November 10th, 1893.

### FAVERSHAM CHRYSANTHEMUM SOCIETY.

THIS comparatively young Society is fast making headway in the district. The Committee announce their Show for this year to take place on the 15th and 16th November, and are sending out details of a new venture somewhat on the lines of the N.C.S. challenge shield. It is to be called the Kent County competition, and is open to all Chrysanthemum and horticultural associations in the county of Kent. The class is for thirty-six blooms, to consist of twelve distinct flowers of each of the following varieties:—Incurved, Japanese, and Reflexed. Kent is noted for some of our best growers, and in the Faversham district we have seen very fine specimens of the reflexed class; still we are inclined to think that if the new class had been for, say, eighteen incurved and eighteen Japs, a more attractive display might be expected. The prizes are good, and Mr. C. E. Clinch of 3, St. Ann's Road, Faversham, is the Hon. Sec.

### THE N.C.S.—“SLIPS”—MR. GODFREY'S LETTER—TORTIOUS.

MAY I venture to put you right on one point, and you have several times made the same slip in the course of this correspondence. You speak of Mr. Godfrey's letter being in the hands of the Treasurer. I presume you mean Mr. Ballantine, who is Chairman of Committee. The Treasurer is Mr. Starling, and nothing short of a row about the reserve fund would draw him into print. I notice in my letter (page 97) your printer's devil does not know how to spell “tortious,” he is evidently not a lawyer.—G. S. A.

[We desire to have all our “slips” corrected. It was not Mr. Starling, the Treasurer, but Mr. Ballantine, the Chairman of Committee, who was pleased to have Mr. Godfrey's letter, and he very clearly intimated that it would be better to inquire into the subject at issue without the publication of the letter. In this we concurred, and on the understanding that the inquiry would be as frank and fair as the majority of the members of the N.C.S. would naturally wish, the matter was left in his hands.

Mr. Godfrey still rests under the reproach of making an untruthful statement respecting a member of the Floral Committee. If a genuine investigation had proved that Mr. Godfrey had no reasonable grounds for his statements we should have expressed our strong disapproval of his conduct, and apologised for having been made the medium in placing the matter in the hands of the Chairman of the N.C.S.

We cannot do anything of the kind at present, as, confessedly, there has been no real investigation; on the contrary, there appears to have been a tacit shielding of one of the parties in the case, and if the Chairman has no objection we will publish what he said on a matter that evidently influenced him in this connection.

In respect to the word “tortious,” our P.D. is “not a lawyer,” and we doubt if he will become a good one as taught by this discussion. The peculiar use of the word “libel,” which, like the sword of Damocles, has been held aloft, has not, however, frightened him, and he thinks “tortious” (crooked or twisted) not an inappropriate term in this reference, though “tortious” (injurious, wrongful) ought to have appeared on the page cited by “G. S. A.” The case of *Godfrey and another* will never be settled satisfactorily until the verdict goes forth that the complainant had or had not reasonable grounds for his allegations. That is the point, and we have no wish to publish anything beyond it.]

### INCREASED SIZE OF STANDS.

I DO not think “D.” (page 76) read my previous note carefully. In my remarks anent the increase in the size of the stands I distinctly say, “Let it be optional and with a provision as to the limit of the extension.” Nothing could be plainer than this. Will “D.” explain where it has already been so conclusively shown that there is no need whatever for the increased size of the stands? If I mistake not he was one of the first to agitate for the increase that he now seeks to condemn. I think he will find when the audits appear that the large varieties were still conspicuous on the exhibition table.

There may be a slight alteration in the figures of some, but that is more owing to inability to produce them, consequent on an untoward season, than anything else. It will be many years before varieties like Vivand Morel, Etoile de Lyon, Boule d'Or, and Stanstead White are relegated to the rubbish heap, or even from the exhibition room, in favour of those of more refinement as suggested by “D.” Could he name one possessing more of the latter quality than a well developed bloom of the first named? This is one of the giants as I understand them.

I fear Mr. Brown (page 76) also does not grasp the real advantage of an increase in the size of the stands. The object in having more space is to reveal the defects in the bloom, if there be any, so that each exhibitor may have justice done to them. Does Mr. Brown uphold the

principle of small stands, because, as he states, where the blooms are packed together such defects are hidden? Surely this would not be justice to another competitor who had perhaps his whole collection without a fault, even though they were so closely packed on the stand as not to allow an opportunity of looking for defects. Neither would it be right to permit these opportunities to hide defects to pass by without any attempt to alter the method of staging.

If one exhibitor can properly fill a larger stand, is it fair to compel him to stage his blooms on a stand much too small for them? Surely not. Again, if another exhibitor cannot well fill an ordinary stand, why should he be compelled to employ a large one, simply because some few think an "absolute rule" is necessary? This dictum of Mr. Brown is not in accord with the convenience that committees are able to allow in their staging arrangements. But if my plan were adopted, there need be no complaints from persons who wished—and could well fill larger stands, both to the credit of themselves, advantage to the judges, and a greater attraction to visitors. Those who are content to cultivate medium-sized blooms, perhaps of small varieties, would not be compelled to employ stands much too large for their productions.

I was not aware that judges had any antipathy to the green boards showing between the flowers. I was a listener to a reprimand which the judges received during the late season at a show, because they had awarded the first prize to blooms which were upon a stand of increased size (where the green board was visible in many places), in preference to the blooms on an ordinary sized stand which was quite covered, and indeed many of the flowers overlapped each other, thus hiding defects. Surely this is not in support of Mr. Brown's argument. The first prize stand in the exhibition alluded to was looked upon as a splendid "object lesson," one certainly that was more creditable to the exhibitor than any other, and acknowledged as such by exhibitors present. If I mistake not, the person in question would require much persuasion to go back to the orthodox stand, even in spite of the antipathy of judges to green paint.—SADOC.

WE outside members of the National Chrysanthemum Society must expect little, I think, from past experience. Starting with a conference upon the increased size of show boards, and after a majority decides in favour of such, the proposition is deliberately cast aside without further appealing to its members. I never heard of any other than the N.C.S. ignoring the decision of a majority of its members before. Perhaps Mr. Jameson, who claims to be the chief mover in the matter, will again revive the subject. Had the N.C.S. adopted the plan I advised—i.e., send to each member and each affiliated society, they would have obtained the opinion of all those the subject most concerns, then they would have had no fear whether they were going to lose support or not.—J. D.

#### PROFITABLE CHRYSANTHEMUM GROWING.

THE list of profitable varieties might of course be greatly extended, but I should say few trade growers will find much difficulty in adding most of those mentioned by Mr. Pithers (page 54). Of the number I had intended to include President Hyde, but by some oversight I had omitted it. It is one of the best yellows for the purpose named. Massalia, which is also named by your correspondent, is evidently a gem of the first water, and his description of its charm is sufficient to make the average market grower's eyes sparkle. About Gloire de Rocher I am not so sanguine. Mr. Pithers would seem to imply that its resemblance to Val d'Andorre is a recommendation, but from the market grower's point of view I do not think it is. Val d'Andorre has been tried by every market man I know, and the result was invariably the same, that is, it had to be discarded after the first season. I am disposed to think that Chrysanthemums of this type have been carefully weighed in the balance and decidedly found wanting in the qualities that go to make saleable cut blooms for market.

I am inclined to agree with your correspondent's statement about the superiority of Madame Louise Leroy over Elaine, and I have little doubt that most market growers favour this view. The former variety can be kept longer than Elaine without getting faded, besides several other good points, but the grower is not exactly a free agent in the matter. Elaine has held so long the position of leading market white that it is difficult to supersede it. Our returns for this season show that Elaine still secures better prices than the other, and I do not think our experience is other than general. That being the case, the market grower has no alternative than to grow it in quantity. Madame Louise Leroy may eventually supersede Elaine, but the process will take time; meanwhile I incline to the idea that there is ample inducement to grow both Chrysanthemums for saleable purposes.—ENFIELDIAN.

#### WHAT CONSTITUTES AN AMATEUR.

THE true definition of an amateur has long been a debateable point in horticultural matters. If we put any faith in a good English dictionary something is to be learnt there about the much-vexed question of what is an amateur. In my copy an amateur is described as a person "who cultivates any study or art from taste or attachment, without pursuing it professionally." Now, I take it that the latter term means anything gained monetarily by professionalism. My idea of an amateur is a person who cultivates any kind of horticultural produce merely for the love of the object, whatever he takes in hand, and not for gain in any way, and one who does not receive assistance from a professional in its cultivation.

Acting in the capacity of Secretary to a rural horticultural Society, where the amateur element is rather strong, I have ample opportunities of ascertaining the methods adopted by this class of cultivators. I find that the wording of the definition of an amateur as employed in our Society seems to meet all cases here. It is thus: "Persons who neither follow the business of a gardener, nor habitually employ a paid gardener in their service solely to attend to their garden, nor are dealers in horticultural produce." Worded thus a clergyman, doctor, school-master, or an ordinary farm labourer for the matter of that, would all be eligible to compete for prizes, and would not be debarred from employing a casual labourer to dig the garden, for instance, at any time.

In my opinion it is difficult to get a better solution of the term than somewhat on the lines here indicated. I have never been in harmony with those who consider that my lord, or duke somebody's gardener is an amateur because he can compete as such at any exhibition of the Royal Horticultural Society. The proposition seems absurd.—E. MOLYNEUX.

#### GRAPES AT FLOORS CASTLE.

I WAS very pleased to see in your issue of January 12th an illustration of the Grape room at Floors Castle Gardens. One point that struck me was the apparently fine berries—if one can judge by a photograph—and considering that the Vines must be now over thirty years old they sustain their vigour well, as I suppose they are those planted by Mr. Rose. It is near thirty years since the writer made the acquaintance of Floors as a young man, and the Vines were then at their best, being about four years old. Three span-roofed houses—one devoted to Muscats, the others to Black Hamburgs, and the third made up of late kinds—were as fine as could be seen anywhere. But although these houses were so fine for general crops there was an early house at Floors at that time that was as unsuccessful. It was a lean-to beside the Pine stove, and the Vines always broke prematurely, and I did not see a decent crop on them. I have never had any difficulty with an early house, and never saw such a capricious case. Some special local influence must have been the cause of this irregularity.

This just reminds me of a little incident regarding Muscat Grapes. One of the still-room maids at Floors once said to me respecting fruit in the Castle, "I wonder how it is that the Muscat Grapes from Broxmouth—the Duke's other place in East Lothian—won't keep, when those grown at Floors would hang till they shrivelled?" But this will break the ice on another subject perhaps, as it may lead to a dispute that arose as to the Broxmouth fruit being Muscats at all, and a bunch was sent to your office to decide. It will be about thirty years ago, though I cannot recollect to a year. When cuttings of these "Muscats" were proved, the matter, I believe, was not disputed, but that the difference in the character of the fruit was from a local source.

I was also pleased to see Mr. Barnes' note in your issue of the 26th ult., to know the exact place where the Grapes are kept, as he may well understand that a young man who was in the bothy nearly three years will know its whereabouts. The bottling system, of course, was comparatively unknown thirty years ago, and there is a very great change in the money value of Grapes then as compared with now. I have seen very good Muscat Grapes hanging on the Vines in March at Floors; they were a little shrivelled certainly, but they were good in colour, and certainly fine fruit.—M.

#### GARDENERS' ORPHAN FUND.

THE fifth annual general meeting of the subscribers to the Gardeners' Orphan Fund was held at the Cannon Street Hotel on Friday, February 3rd. In the unavoidable absence of Sir Julian Goldsmid, Bart., M.P., the President of the Fund, Dr. M. T. Masters, F.R.S., presided. There was but a small attendance, doubtless owing to the thick black fog which prevailed at the time. After reading the minutes of the previous meeting, the Hon. Secretary produced the Executive Committee's annual report and financial statement, which were unanimously adopted, as follows:—

##### ANNUAL REPORT AND FINANCIAL STATEMENT.

The Executive Committee have great pleasure in presenting their fifth report, and in congratulating the subscribers to the Gardeners' Orphan Fund on the closing of another successful financial year, and the continued prosperity of the charity.

The claims of the Fund having been brought under the notice of Her Royal Highness the Princess of Wales, the Committee have the honour to announce that Her Royal Highness has been graciously pleased to become patroness of the Fund, and has expressed the hope that "the fact of her name appearing as patroness may assist the objects of the charity." Such exalted patronage being extended to the Fund is most gratifying to the Committee, and will be of the greatest value and importance in the promotion and furtherance of the cause.

The munificent donation of £500 from Mr. and Mrs. Harry J. Veitch, as a thank offering on the celebration of their silver wedding, was an act of generosity unexampled in the history of gardening charities, and the warmest thanks of all concerned in the welfare of the Fund are due to them.

The Committee are under deep obligation to Sir James Whitehead, Bart., M.P., for his great kindness in presiding at the annual dinner at the Hotel Métropole (which was a new departure in the management of the Fund), and whose eloquent appeal for support resulted in the sum

of nearly £1000 being received on that occasion. The Committee hereby tender him a most cordial vote of thanks.

During the past year fifty children have been receiving the benefits of the Fund, and the Committee recommend that eight be elected this day, bringing the roll up to fifty-eight. Two of the orphans on the list—viz., Victor Spyers and Ralph Joseph Gardiner—having attained the age of fourteen years, are no longer chargeable to the Fund. See Rule XIII.

The Committee again take advantage of the presentation of their annual report to tender their most sincere thanks to the many kind friends throughout the country for efficient help rendered in many ways, but whose names it would be invidious to mention.

A slight falling off occurs in the annual subscriptions, which is to be regretted, as this should form the chief source of income. The Committee appeal strongly for increased efforts in obtaining new subscribers and more earnest support from the gardening community generally, in whose interests the Fund was established and is maintained.

The Committee have to lament the death during the year of Mr. C. H. Sharman, one of their most zealous and active colleagues, who took a very warm interest in the Fund from its commencement. The Committee have elected Mr. Robert Ballantine, as a member of their body, in the place rendered vacant by the death of Mr. Sharman.

The members of the Committee who retire by rotation are Messrs. Head, Laing, Nicholson, Poupart, Smith, Walker, and Turner, who, being eligible, offer themselves for re-election. The retiring Auditor, Mr. John Fraser; the Treasurer, Mr. T. B. Haywood; and the Hon. Secretary, Mr. A. F. Barron, are nominated by the Committee for re-election.

(Signed)

JOHN FRASER, *Leyton,*

WM. SHARP, *Chartered Accountant, 60, Gresham Street, E.C.* } *Auditors.*

Dated January 13th, 1893.

Dr. Masters, previous to the adoption of the report and financial statement, remarked that there were one or two points that called for comment. First it was the small attendance, but that might be taken as a guarantee of the good faith subscribers have in the Executive. Another point was the fact that H.R.H. the Princess of Wales had consented to become Patroness of the Fund, which could but do good to the organisation. It was also a matter of gratification to know that Mr. and Mrs. H. J. Veitch had subscribed so liberally to the Fund, as a thank-offering for the celebration of their silver wedding. He noticed, however, that according to the report there was a slight falling off in the subscriptions, which was a matter for regret and not creditable to gardeners.

The retiring members of the Committee, as mentioned in the report, were unanimously re-elected, as likewise were Mr. T. B. Haywood as Treasurer, Mr. A. F. Barron as Honorary Secretary, and Mr. J. Fraser,

Leyton, as Auditor, with Mr. W. Sharpe, Chartered Accountant. It was also proposed by Mr. J. Wright that Sir James Whitehead, Bart., M.P., and Sir Edwin Saunders be elected Vice-Presidents of the Fund. This proposition was unanimously adopted.

Messrs. R. Dean, Poupart, J. Weeks, and B. Wynne were then appointed Scrutineers for the poll for the election of eight candidates for the benefits of the Fund. The poll closed at four o'clock, when the following results were announced, those with an asterisk affixed to their names being elected:—\*Ada Beddock, 228; Winnifred Helen Doherty, 59; \*Nellie Ede, 254; Robert Houston, 185; John Keates, 52; Alice Maud Milne, 81; \*Minnie Rapley, 195; John Titley, 114; Rosa Emily King Ward, 143; Robert Clement Blake, 154; \*Otto Kosbab, 217; \*John Mitchell, 227; \*Emily Kate Neve, 220; \*Frederick Price, 445; \*Philip Arthur Stevens, 216.

In the evening, and at the same hotel, the members of the Committee and a few friends had a friendly dinner, Mr. W. Marshall presiding.

#### EXPERIENCE IN HEATING.

TAKING Mr. Craven's article (page 87) as a whole it must prove instructive to those who have had but little experience of the subject. It is not to be expected, however, that even all Mr. Craven has to say upon the question will be universally acknowledged as correct and conclusive. The subject of heating horticultural structures by the aid of hot water is a wide one and one that contains considerable range for debate. The remarks made by Mr. Craven at the commencement relating to the density of cold water over that which is warm can very quickly be tested by anyone having a tank heated with hot-water pipes, for where these are not fixed at the bottom of the tank there will be found to be at least 40° difference between the temperature of the water at the bottom of the tank and that at the top. This is a very good proof of how slow the cold water is to mix with that which is warm when there is no propelling force, as in the case of the fire under the boiler.

The danger from rising water in the stokehole can easily be averted by a little expense. As a rule, the stokehole is brick-built, although I know some that were hewn out of the solid rock and others dug in the chalk. Seldom in either of these instances will there be any trouble with the rising water. The way to avert this is to build first the 9-inch wall in cement instead of ordinary mortar; afterwards cement the sides and bottom of the stokehole as you would a tank, first having laid a floor of concrete, over the top of which is cemented. Mr. Craven gives several illustrations of how the hot-water pipes in the early fruit houses can be arranged. This will, no doubt, prove useful; but so much depends upon the position of the house and the manner in which the mains run that no absolute rule can be laid down. My experience of a sharp vertical rise in the pipes connecting with the main is that at 4 feet the circulation is perfect, and from the easy manner in which the water travels, I should say another foot would hardly make any difference in the circulation of the water.

My experience of six pipes in one house is that five flows, all working from the connection at right angles, is most satisfactory, these all converging into one return pipe at the opposite end, and running parallel to the flow at the entrance. I do not consider that two flows along the front of the house is the best way of arranging the pipes. This system of fixing them is more likely to hurry on the Vines at that part of the house, and also to be the means of bringing about a full crop of red spider over the pipes; whereas if they were spread more equally over the house the heat would be equalised throughout the house. I quite approve of the plan of having a valve on both the flow and the return pipes. If this is not done the water is sure to "back up" far too much at times, but sometimes the cost of extra valves prevents this plan being carried out. I find simple throttle valves are of little use in holding back the hot water.

A better plan of supporting the pipes across the border, where this is inside the house, than that of building brick piers, is that of supporting them with light iron girders resting on a pillar at the side next the path and the opposite end let into the front wall. Where the borders are 3 feet deep the cost of building the piers will be much more than the cost of the iron girders; these latter do not take up the border space either.

Mr. Craven does well to point out the advisability of heating the water in the tanks inside the houses. This is a boon to gardeners, but, unfortunately, too few participate in it. It is surprising how quick a tank holding 600 gallons of water can be heated up to 90° with just a flow and return 3-inch pipe connected by one 2 inches in diameter to the main. I prefer the inside of the evaporating troughs painted stone colour; the red, which makes them look "smart," would be objected to in many vineries.

With regard to the packing of the joints I think there is none like those properly made with iron borings. After fourteen years' hard wear I cannot see the slightest sign of a leak, nor has there ever been one in my pipes. There is one objection to this form of making joints: the difficulty of picking them in case of an accident or alteration. For this reason spun yarn and red lead is perhaps to be preferred when well done; but if not so they are certain to leak.

For giving a regular bottom heat, I think there is nothing like a tank with hot-water pipes running either through it or round it. The heat is so much more genial for the purpose, being moist. It is not necessary to have more than 2 feet of water in depth, but the width can be as much as thought fit. As a propagating convenience, there is

nothing like the moist heat arising from a tank. I find anthracite far superior to any other kind of fuel. Not only does it effect a great saving in the yearly bill, but also in labour in stoking. The best proof of this is the desire of the stokers for a supply of this coal in preference to coke.

I find draw-off pipes from the boiler plenty large enough if an inch in diameter. As a rule they are not connected low enough to the boiler. The object of having these draw-off pipes is to periodically cleanse the boilers of sediment which collect in the corners of those of saddle shape. If these pipes are fixed 4 inches or 6 inches from the base it is impossible that all the sediment can be taken from these most dangerous parts. It is generally there that these boilers exhibit their first defect. Some hot-water fitters only connect a pipe on one side of the boiler; this is useless for the opposite one. The best form of outlet is a plug screwed into the end of the pipe, which is generally built into the wall and allowed to project an inch or so. When the boiler is emptied it should several times be washed out by closing the flow valve until the boiler has drained off, then allowing more water to rush into the boiler with some force, the sediment at the base is stirred up, the bulk of it will then run out of the pipe if this latter is close to the bottom of the boiler. Where chalky water has to be used a cleaning out is oftener needed than when the water is less hard.—E. M.

### ALOCASIA MACRORHIZA VARIEGATA.

NOTWITHSTANDING recent introductions this *Alocasia* when well grown remains a most telling plant for the decoration of our stoves. There are different ways of cultivating it, some growers treating it as they would a *Caladium*, others keeping the plants growing throughout the winter. When plenty of heat is at command I much prefer the latter system, as then there is not nearly so much risk in losing the bulbs as when they are dormant, while the cultivator gets an earlier start when potting time arrives. If they are to be grown as single crowns old plants may be turned out of their pots, and the medium-sized crowns selected for the 6-inch pots, reserving the stronger to be placed five or six in a 12 or 14-inch pot, and the weaker ones for pots about 3½ inches in diameter.

The compost we use with every success comprises three parts good sound fibry loam and one of dried cow manure, broken into small pieces, with plenty of coarse silver sand and a few pieces of charcoal to keep the right amount of porosity. The pots they are to be placed in must have been previously washed and carefully drained. Place some of the rougher portions of the compost over the drainage, and then fill up to about three parts with the compost. On this put the crowns, and merely cover the roots with soil; insert a small stake and tie with a piece of matting to keep it steady until the roots have got a firm hold into the new soil. If there is a little bottom heat at command the plants should be plunged and carefully watered until root growth commences. When fairly established and the white fleshy roots appear on the surface of the soil, fill the pots with the same compost, and as this in turn becomes permeated with roots weak supplies of liquid manure at intervals will do much good in building up solid crowns. During the summer the plants will require large supplies of water at the roots, but as the autumn comes round the supply may be lessened, and just sufficient to keep up root action will suffice during the winter.

If the bulbs are now dormant it would be well to shake them out of the old soil, and put into smaller pots, using a mixture of leaf mould, sand, and charcoal, or in place of leaf mould a small proportion of loam. Plunge them in a genial bottom heat, and keep the soil fairly moist until growth commences. They may then be placed into larger pots, using the stronger compost, as recommended for those which have been kept growing through the winter. During the summer care should be taken that moisture is not allowed to rest upon the foliage when placed in the direct sunshine, or the leaves will soon be scalded, a condition which entirely spoils the appearance of the plants.—R. P. R.

### NOTES IN SEASON.

To guard against any scarcity of produce in the spring and early summer we have sown seeds of Cabbage, Cauliflower, Lettuce, and Parsley under glass, in soil that has been emptied out of the *Chrysanthemum* pots. We sow thinly, cover slightly, and keep the soil moist. The seedlings soon appear in gentle warmth, and are kept as near the glass as possible to insure sturdy growth. When the seed leaves are developed the plants are pricked 4 or 5 inches apart in boxes about 2 feet 6 inches long, 18 inches wide, and 6 inches deep. Much the same soil is used, with the exception that we place a good coating of old Mushroom bed refuse over the drainage. When the plants commence growing air is admitted on every favourable occasion, gradually hardening them until they can be safely placed in pits or frames, protected with mats in severe weather. We always keep a few boxes of Lettuces and Parsley in one of the greenhouses, and use from them; those placed in the cold frame coming in useful for planting outside.

Carrots and Radishes are raised in a frame on a mild fermenting bed on which soil 6 inches deep is placed. The seeds are thinly sown broadcast, the Radishes being ready for use and out of the way long before the Carrots are fit to pull. As regards varieties most persons have their own particular choice, and those specially recommended by seedsmen of high repute are reliable.

Rhubarb should be ready when wanted; it is forced with sweet

leaves in preference to stable manure, as in the latter much of the brisk acidity of the Rhubarb is lost. By taking up a few roots of Mint and placing them in boxes in a little heat a crop of green shoots soon follows, and they are much appreciated. With a little forethought vexations through a scarcity of garden produce may be averted. We cannot all be perfect, but exchanging views and offering suggestions in a friendly way is pleasurable, and scattered hints are sure to be useful to some readers.—R. P. R.

### SNOWDROPS.

MR. S. ARNOTT'S article on pages 21-22 will, I doubt not, cause many lovers of these hardy gems to search for novelties—not only amongst Snowdrops, but other flowers as well. Variety is not always found amongst seedlings. The single *Narcissus poeticus* and other varieties have produced double forms, or are in progress, which took place after they had been moved while in bud. Fasciation, and constricted stems or branches, sometimes produce abnormal, large, or curiously shaped flowers, and not unfrequently double blooms. I will not attempt to explain the cause, but simply ask a question. Are the nitrogenous pollen-bearing anthers converted into petals when the flow of proper nourishment is restricted, and do petals require less support for their development than anthers? I have been prompted to make these remarks from observations I have made on plants after manipulation and mutilation of bulbs, roots, and branches.

I have grown the Crimean Snowdrop for upwards of thirty years. At first it was the last to flower, blooming as late as the end of April; but it is gradually losing that character, and at the present time it is as far advanced as *Galanthus nivalis*, while the flowers are variable, showing plainly that soil and climate are taking effect in working a mysterious change.

About twenty-five years ago I moved 20,000 Snowdrops during February, planting them in lines. For two years they did well, giving promise that the shift during the blooming period was a success, but my hopes were soon blighted, as the third year there was scarcely a bloom, and the foliage weakly, and the fourth season there were not more than a thousand bulbs remaining. I at first thought slugs had been at work, through the starch of the bulbs being converted into sugar, as is sometimes the case with bulbs that have been lifted, but in this case it was not so, as the bulbs were not mutilated; there was simply no growth either of roots or foliage.

It appears to me that Snowdrops are sensitive, and suffer from being moved at any time other than when both foliage and roots are dead. If lifted at any other time a precocity starts them into flower, the roots refuse to push forth, the foliage is stunted, no bulblets are formed, and the Snowdrops disappear.

Several years ago I planted some bulbs of the Giant, but they refuse to increase. In the summer of 1892, among other things I had sent me by Mr. S. Arnott, were bulbs of *Galanthus Elwesi* and *G. Fosteri*. One bulb of *Elwesi* showed bud at the end of December, but owing to the severe weather the flowers did not open till the 20th of January, when without sunshine the thermometer stood at 48°. Why this precocity? All the rest of *G. Elwesi* planted at the same time and place, and the same depth, will be at least two weeks later.—W. THOMSON, *Blantyre*.

### RUSSIAN APPLES.

MOST of the varieties, as given by Mr. Hilborn in the annual report of 1888, have made very satisfactory progress up to date. Thirty-five of the later importations of the Iowa Agricultural College were received from Professor Budd last spring, and were added to the original planting, making in all 215 Russian varieties on trial. This orchard was the first to fruit on the experimental grounds, a number of trees giving specimen Apples this year. Some of them are large, and of fair quality, but further experience is needed before a true estimate can be made of their value. In this connection it may be added that the large and interesting collection of Russian fruit on the farm of the late Charles Gibb of Abbotsford, Quebec (now owned by Wm. Craig & Son), has been, by your instructions, under my observation during the fruiting season of this year. The planting of Russian fruits was begun by Mr. Gibb about ten years ago. Many varieties are now coming into bearing, and it is hoped that by careful observation of the success of the different varieties in that district, a reliable opinion will be arrived at in regard to their possible success and usefulness in the colder parts of the Dominion. The fruit growers of the Province of Quebec, especially, had for years been watching with much interest the self-imposed task of fruit testing—"for the cold north"—undertaken by Mr. Gibb, and it will be a source of satisfaction to them to know that the results which he came so near attaining, will not be lost to the people in whose interest he laboured. It is hoped that, with the added experience of another year, sufficient information will be acquired to enable such facts to be published in bulletin form, as will serve as a guide to planters along the northern limits of present Apple culture; for this is the region where the Russian Apple will be of greatest service. Another purpose which this race will serve, and which will be developed later, is that of giving us hardy stocks for top-grafting. Many varieties already fruited, judging from their poor quality, should be condemned, but will be retained, for the purpose just indicated, on account of their great vigour and hardiness. They will also undoubtedly be the progenitors of a

hardier race of Apples than we now have, by crossing with our American sorts, or by seedling production.

The following list is based upon the observation of four years on the grounds of the Iowa Agricultural College, and the experience of last summer at Abbotsford. The varieties mentioned are commended to the careful attention of fruit growers.

*Zolotoreff*.—Large, conical, rich carmine, with light dots and stripes on the shady side. Calyx open, basin wrinkled, stem short, cavity deep, narrow. Flesh yellowish white, tinged with pink when over-ripe, rather coarse in texture, quality medium. Season early September. A fine handsome Apple. The tree is a vigorous upright grower, with large glossy leaves. Hardy as Duchess. Closely resembling this in tree and fruit are Basil the Great and Titovka.

*Golden White*.—Large, oblong, ribbed, yellow ground, covered with bright red towards cavity, calyx open, basin slightly wrinkled, somewhat ribbed, stem short, thick, cavity small, in some almost closed. Flesh white, crisp, tender, juicy. Sub-acid sprightly, very good season, August to September. Keeps better than Duchess. Claimed by some to keep till midwinter. Tree a good grower of upright habit. Very hardy.

*Arabka* (imported by Ellwanger & Barry).—Large, oblong, irregularly ribbed, dull red on sunny side, shading to dark green. Calyx closed, basin shallow, deeply wrinkled. Stem short, thick set, in closed cavity. Flesh greenish white, rather coarse, mildly acid. Season November to March. In the west the tree has been somewhat subject to blight, but it has not been affected this way in the east. In hardiness it may be graded with Wealthy. This will undoubtedly be valuable in the colder districts. Trees planted ten years ago at Abbotsford have been bearing heavily and regularly the last four years. The Arabka imported by the United States' Department of Agriculture is quite different—an early fall Apple of the Duchess type, very vigorous and hardy.

*Gipsy Girl*.—One of the hardiest and most vigorous of all the Russians. Specimens were taken this season from trees planted two years ago on the Experimental Farm. The fruit is large, highly coloured, of fair quality, and keeps till February. Wherever this tree has come under my notice it has been doing well.

*Royal Table*.—This Apple is of North German origin, the later importation by Professor Budd. The trees at Abbotsford are compact growers, with round topped heads, slender twigs, and medium-sized leaves; they have made vigorous growth, and seem perfectly hardy. Fruit medium to large, conical, ribbed, greenish, with dull red stripes on the sunny side, calyx open, basin wide, wrinkled, stem short, thick, cavity wide, shallow, flesh greenish white, inclined to be tough, quality fair. Season: at this date (January 25th), specimens in my cellar are firm and in good eating condition. It should keep through February. As already stated notes were taken on a considerable number of varieties which fruited at the Experimental Farm and at Abbotsford the past year, but it is thought better to reserve such information for future publication.—JOHN CRAIG, *State Horticulturist, Ottawa*.

#### THE KITCHEN GARDEN.

**Potatoes in Pits and Frames.**—Now that early Potatoes can be bought so cheaply fewer attempt to force them than formerly; but all the same, home-grown tubers are usually superior in quality, and are always appreciated. To meet the demands of large establishments, whole rows of frames or pits have to be given up to early Potatoes, while those in charge of small gardens can only devote a very limited number to this work, early dishes being provided for special occasions only. What is wanted is either a gentle hotbed of leaves or leaves and manure in heated pits of sufficient depth to raise the soil well up to the glass; and in the case of deep garden frames only being available, these should be set on a hotbed 4 feet deep at the back, with a good slope to the south. In this instance again a mixture of stable manure and leaves is to be preferred, this being the least liable to become dangerously hot when warm weather sets in. If stable manure only is available, well prepare this by throwing into a heap to ferment at least a fortnight before using, giving it one or two turns in the meantime, and do not make the bed quite so deep as when leaves are used. Half fill the frames with some of the shortest of the manure, on this placing about 9 inches of light sandy soil, or such as can be obtained by sifting over a heap of old potting compost, notably which has been used for Chrysanthemums. The same depth of soil should be placed in the pits, and in either case wait till this is well warmed through, and the bed underneath has cooled down, so that the trial sticks kept plunged in it can be comfortably borne in the hand before planting the already sprouted sets. Any short-topped early variety is suitable for forcing in frames, though none surpasses the old Ashleaf in quality. When planting open drills about 15 inches asunder and 5 inches deep, in these place the tubers 6 inches apart, levelling the soil about them without damaging the tender and already well

rooted sprouts. Keep the pits or frames fairly close, a little opening being left for the escape of vapour, giving more air when the shoots are through the soil. Cover frames with mats and litter every night, and in heated pits turn on only a very little fire heat.

**Frame Culture of Peas.**—Peas do not stand forcing, but may be forwarded considerably. They can be gathered earliest from plants in properly glazed pits and large frames; but better crops, if later, can be had with the aid of rough pits or frames, at least a fortnight being gained when these are used. The varieties best adapted to frame culture are Chelsea Gem, William Hurst, and English Wonder, the last named requiring the least room, and cropping admirably. Sow about 1 pint of seed thinly in small pots or in boxes filled with light soil, and place in gentle heat, an early Peach house answering well. By the time the plants are 3 inches high, and have been slightly hardened off, the pit or frame should be ready for their reception. Give them the benefit of a shallow mild hotbed of short decaying manure, on this placing 9 inches of rather good loamy soil, deferring planting till this is well warmed through. In planting arrange the rows 15 inches apart, putting out those in pots with a trowel, while those in boxes should be carefully shaken out of the soil, and planted with their roots down straight in narrow trenches. Fix the soil firmly about the roots, and make all level preparatory to dibbling out a row of either Early Paris Market or Golden Queen Lettuce midway between the Peas. If the soil is at all dry give a gentle watering with lukewarm water, but if already in a moist state defer watering till it has become drier. Glazed lights being available keep these close till the Peas and Lettuces are growing afresh, gradually hardening off the two latter, so as to be able soon to make good use of the lights elsewhere. Failing glazed lights roughly protect with mats. Lightly stake the Peas before they fall about. The Lettuces alone will more than pay for all the trouble taken.

**Peas for Planting in the Open.**—The earliest crops in the open can be had by raising a good stock of plants under glass, and planting these out on the first favourable opportunity. The dwarf varieties already named are the best for the purpose, William I., Exonian, and such like affording a good succession. At least one quart of seed ought to be sown in order to be sure of enough Peas to plant rows equal to a length of 36 yards. They move well out of shallow boxes filled with light soil, and this is the simplest plan of raising them. If preferred, either small pots or turves may be used. A very little heat will suffice to bring them on as soon as the weather will permit their being turned out with safety. If Telephone, Duke of Albany, or any other moderately early Marrow Pea is desired extra early, enough plants for filling a good row should also be raised under glass, but not in strong heat.

**Sowing Peas in the Open.**—During the first fortnight in February, weather and state of ground permitting, some of the earliest round-seeded Peas may well be sown, the produce from these forming a close succession to that obtained from the planted-out rows. The more delicate wrinkled seeded varieties ought not, as a rule, to be sown yet, these being more liable to decay in the ground. A south border or a good slope to the south, but well away from the walls, answer best for these early crops, the ground being well manured, and if at all bad working, brought into good condition. Most of the early round-seeded varieties attain a height of from 3 feet to 4 feet, and the latter distance may well be allowed all of them. Where there are long borders available these may be turned to the best account by arranging the rows of tall Peas 10 feet apart, either sowing or planting four rows of dwarf Peas, Beck's Dwarf Green Gem Bean, Cauliflowers, or Potatoes between these. For the Peas open drills 2 inches deep, sow the seed rather thickly, and cover with fine soil. If there are mice in the garden coat the seed with red lead prior to sowing it.

**Broad Beans.**—Much that has been advised in the matter of raising and sowing Peas also applies to these, though it is not often that it is necessary to raise plants under glass. If the rows of autumn raised plants are patchy either make these good by transplanting two or more rows into one, or else raise the requisite number under glass—preferably in small pots—and plant out before they become root-bound. For present sowing Early Longpod and Beck's Green Gem are to be preferred, disposing the seed thinly 2 inches deep in drills 2 feet apart.

**Spinach.**—Autumn sown crops have escaped destruction from frosts, and if a little soot or other fertiliser is carefully sown among the rows and stirred in with a flat hoe an early and strong growth of leaves may reasonably be anticipated. More seed should now be sown, suitable positions being between the rows of newly sown Peas.

**Parsley.**—Frosts have destroyed many of the roots and badly crippled the rest. Unless there is abundance of young leaves forming under glass some of the soundest of the roots should be lifted, placed in large pots or in deep boxes, and gently forced. Also sow seed either on a gentle hotbed—much as early Carrots are sown or in boxes, placing the latter in heat. Some of the plants thus obtained may be kept under glass and the rest dibbled out, a supply of early leaves being the outcome.

**Carrots and Radishes.**—Early Carrots are always appreciated, and so also are Radishes in most cases. Both may be grown together without interfering with each other. Of the former, the quickest to attain a serviceable size is the Parisian Forcing, Early Horn and Nantes Horn also forcing well. Radishes—French Breakfast, Short Top, Red and White Forcing, and Wood's Frame, all force admirably. At this early date moderate deep hotbeds, of not less than 4 feet deep at the back, and facing south, should be formed of leaves and manure, the frame being set on this, and half filled with some of the shortest of the heating material, on this being placed a layer 6 inches deep of light

sandy soil. When all risks from over-heating are past, form shallow drills, with the edge of a short measuring rod, 8 inches apart, for the Carrots, and midway between these for Radishes. Moisten the drills if at all dry. Sow the seed thinly, Radishes in particular succeeding best when no thinning out is needed, and cover either by smoothing over the bed or with a little added fine soil. Keep close and dark till the Radishes show through the soil, which they quickly do, after which admit plenty of light and a little air on warm days, covering the frames heavily with mats and litter every evening.

#### FRUIT FORCING.

**Vines.**—*Early Vines in Pots.*—Those started last November have the Grapes advanced in swelling, the bunches having been thinned directly the berries were fairly set, this being essential for acquiring good size in those that are left, but it is equally important to remove surplus bunches early, quality being of more importance than quantity. The laterals beyond the bunches may be allowed to advance a little, say a joint or two at each development, but the foliage only that is exposed to light is of value for elaboration, and crowding must be avoided. Laterals behind the bunches should be closely stopped or removed where they interfere with the principal leaves. Top-dress with a rich compost or partially decayed manure, to receive which rims of zinc 4 inches deep fitting within the rims of the pots should be provided. Liberal supplies of stimulating liquid should be given, not too strong, and an occasional sprinkling of superphosphate on the surface of the soil will greatly benefit the Vines. Where the pots are standing on brick pedestals and fermenting materials are placed round the pots the roots, being thereby encouraged, extend over the rims by turves placed around them, liberal supplies of liquid may be given where the pots are to remain until the Grapes are ripe, as the roots spreading through the fermenting material gather sustenance which greatly aids the swelling of the berries.

*Early Houses.*—The bearing shoots should be stopped when two joints are made beyond the show of fruit and the leaf at the joint is the size of a halfpenny. If the space is small stop one joint beyond the bunch, or even at the bunch, as it is desirable to have some growth beyond the fruit to attract the sap and encourage root activity, stopping the laterals at the first leaf and allowing no more to be made than can have full exposure to the light. Where there is room the bearing shoots may have three or more leaves beyond the bunch. The more perfect foliage a shoot has the finer will be the Grapes, for their excellence is proportionate with the chlorophyll stored in the parts adjacent to the fruit. Laterals below the bunch may be removed where the space is limited, except from the two lowest leaves, and they should be pinched at every leaf. The great point is to secure well developed leaves fully exposed to light. Tie the shoots down carefully, not being in a hurry, but the points must not be allowed to touch the glass.

*Vines in Flower.*—These should have a night temperature of 65°, and 70° to 75° by day artificially, the air of the house being kept rather dry. Thinning the berries must commence with the free-setting varieties as soon as they are formed; but if the Vines are inclined to produce stoneless berries the bunches should not be thinned until the properly fertilised takes the lead in swelling. Remove duplicate bunches, leaving the best and most compact, avoiding overcropping as one of the greatest evils in Vine culture.

*Stimulants.*—Examine inside borders frequently, and when water is required supply it abundantly a few degrees warmer than the temperature of the house. Liquid manure also should be slightly warmer than the mean of the atmospheric heat, and never be applied too strong. Top-dressings should be applied after the soil has been properly moistened and worked in lightly. All salts, such as those of ammonia (sulphate), potash (nitrate), and soda (nitrate) should be very finely ground, for any undissolved particles coming in contact with the roots may cause damage. They are best given along with dissolved bones and gypsum, say five parts dissolved bone or superphosphate, three parts nitrate of potash, and two parts gypsum, mix, and apply 4 to 8 ozs. per square yard. Sulphate of ammonia and nitrate of soda may be given along with Thomas' phosphate powder, say, 7 lbs. of Thomas' phosphate powder and 1 lb. of nitrate of soda, mix, and spread evenly at the rate of 4 ozs. per square yard. Sulphate of ammonia may be used with Thomas' phosphate powder in the same proportion and at the same rate, but the sulphate and nitrate cannot be too finely powdered. The sulphate of ammonia is best for rather strong loams, nitrate of soda being suitable for light and calcareous soils. If the roots are near the surface it is best to apply the salts in liquid form, say 1 oz. to 8 gallons of water, and supply that quantity per square yard, always at the proper temperature. The basic slag or Thomas' phosphate powder may be sprinkled on the surface before supplying the sulphate of ammonia or nitrate of soda in solution. The fermenting materials on outside borders if any has been used must be attended to, and when the heat declines remove some of the most spent, and renew the heat by the addition of fresh leaves and litter. A light mulching may be given the inside border as soon as the Grapes are thinned; there is nothing better than sweetened manure from horse stables, as damage may be done by an excess of ammonia. Close the house early with plenty of atmospheric moisture.

*Early Muscat Houses.*—Since the introduction of that very fine Grape, Madresfield Court, which forces as readily as Black Hamburgh, there has not been so much need for forcing Muscat of Alexandria early, still there is no comparison of the two for Muscat flavour, therefore, where a house of this variety was closed about the middle of December the bunches are now approaching the flowering stage, when they require a night temperature of 65° to 70°, advancing 10° to 15° by day, closing

the house at 80° to 85° in bright weather. When in flower every bunch should have a large, flat camel's hair brush lightly drawn over it, and if there is a deficiency of pollen that of Hamburgs should be collected, as it may be by holding a large sheet of paper beneath the bunches and a rapping them sharply, and if this is applied to the stigmas of the Muscats the berries will set well. It does not answer to drive early Muscats, but allow time for the proper development of the leaves, otherwise they are so thin in texture as to scorch badly under powerful sun. It is also important to have the roots of the Vines inside, to supply them through the growing season with due moisture and nourishment, and so secure stout short-jointed wood, and thoroughly ripened, otherwise early Muscats are unsatisfactory.

*Succession Houses.*—Attend to disbudding when the growths are sufficiently advanced to show the most promising, but proceed gradually with this operation, retaining the best "shows" for fruit—those that promise the most compact bunches. Tie down the young shoots before they touch the glass, stopping as before advised, and allow canes to extend where it is thought desirable to cover vacant space, pinching the laterals at the first leaf so as to concentrate the elaborated juices on the buds in the axils of the principal leaves. Remove surplus bunches before they flower, it will strengthen those retained, and maintain a genial atmosphere by damping at closing time or when required, but avoid a close saturated atmosphere as it does harm by promoting soft growths and aerial roots. If there is any deficiency of moisture in the borders supply water in a tepid state, but there is no need for abundant supplies until the Vines have leaves to assimilate the nutrient element. A wet condition of the soil in the early stages is more prejudicial than otherwise, as it retards rather than favours root formation. The present is a good time to start Vines for ripening their fruit under the most favourable climatic conditions during August and September. Late houses of Hamburgs should be kept cool so that the Vines may start naturally.

*Late Houses.*—Where the Vines were cleared of the Grapes early in January, then pruned, dressed, and have since been kept cool, a start may be made with such as take a long time to ripen, particularly Gros Colman and Gros Guillaume, as it is essential to the Grapes keeping well that they be ripened thoroughly by the middle of September. Inside borders should be brought into a thoroughly moist condition by a good supply of tepid water. Strong rods should be depressed to a horizontal position or lower, and a good break insured by syringing the Vines and house two or three times a day. The night temperature may be kept at 55°, rising 5° to 10° by day, and an advance of 5° or more from sun heat, with free ventilation.

**Cherry House.**—The trees are now rapidly unfolding their buds, and the blossoms will soon have a beautiful appearance. It is wiser to anticipate than await insect infections by fumigating the house before the flowers expand, so as to make sure that the trees are free from insects, or an application of clear rather strong quassia water will answer the same purpose, repeating at intervals of a day or two. The temperature should be maintained at 40° to 45° at night, and about 50° in the daytime regularly, a genial atmosphere be secured by damping available surfaces occasionally. The house can hardly be too freely ventilated, subject to the temperatures being maintained. If fresh trees are to be introduced they must be planted without delay, shading them when the sun is powerful, and lightly sprinkling them frequently to promote their speedy re-establishment, surrounding surfaces also being well moistened.

#### THE FLOWER GARDEN.

**Zonal Pelargoniums.**—Where cuttings have been wintered thickly either in pots or boxes these will require to be given more room soon, or otherwise they will not plant out well next June. First, however, start them in gentle heat, or wait till they commence growing naturally in their present quarters, and then pinch out their points. Directly they break afresh either place singly in small pots or dispose them more thinly in boxes and pans. Thus treated, and kept for a time in gentle heat, they will make strong bushy plants, effective from the day they are put out. On no account cut off the tops of these autumn-struck plants for the purpose of rooting, as it quite spoils them. Place all old plants, notably of bronze, gold, and silver variegated varieties in a vinery or Peach house being forced. This will cause them to grow strongly, and the young shoots when moderately firm root readily. If the tops are taken off before active growth has commenced many of them will fail to strike.

**Heliotropes, Fuchsias, and Abutilons.**—Old plants of Heliotropes ought now to be topped and placed in heat, the side shoots from these being struck as fast as they form. A few Fuchsias, if young plants are required, to be similarly treated, but the bulk of old plants ought still to be resting in greenhouses or other cool quarters, April being quite soon enough to start these. Young shoots of variegated Abutilons taken off with a heel of old wood strike readily in heat, and in order to have plenty of these very effective bedding plants, lightly prune what stock plants there are in pots and start them in heat.

**Verbenas and Lantanas.**—Stock plants of ordinary Verbenas now in small pots and cool quarters should have a shift and be placed in heat. Keep them well away from the hot-water pipes, and free of other insect-infested plants, and a capital lot of sappy sure striking cuttings will then be obtained. Verbena venosa is best propagated by means of root cuttings. Cut the fleshy roots into 2-inch lengths, dibble these in rather thickly into boxes or pans, the topmost joint not being deeply buried, and place in brisk heat. There will soon be plenty of well-

rooted plants ready for boxing off. Both kinds of Verbenas may be raised from seed, mixed beds of seedlings being very effective. Sow in pans at once, cover with squares of glass, and keep in moist heat till the seedlings appear. Sometimes the seed germinates very quickly, while not unfrequently it is several weeks before it does so. Lantanas may be raised from cuttings or seed exactly as advised in the case of Verbenas.

**Koniga variegata and Lobelia.**—Plants of the Koniga should be placed in heat, and the cuttings struck as fast as they can be obtained. If dwarf Lobelias are to be raised, either by division or cuttings, keep the stock plants on a warm greenhouse shelf. Subjected to a strong heat the tops soon become hard and develop into flower heads. Directly the shoots emit roots just above the soil division should take place, every partially rooted piece duly topped soon becoming a strong plant. Only sappy shoots are of any use for making into cuttings.

**Polemonium cæruleum.**—The variegated form of this plant now in frames or other cool quarters will soon commence to emit roots from the short stems, either buried or just above the surface of the soil, and then will be the time to divide them into as many pieces as there are crowns. Place them singly and rather deeply into 3-inch or slightly larger pots, but still keep them in a cool pit or frame, this plant being most impatient of heat, and also of drought.

**Dahlias.**—If it is intended to increase the stock of Dahlias by means of cuttings, young single-stemmed plants being also the best for all purposes, place some of the old roots in gentle heat, and root the cuttings that are produced separately in small pots. They are best taken off with a heel, and before they become hollow. Dahlias can be raised very easily from seed, but seedlings, as a rule, are not nearly so good as ordinary named varieties.

**Cannas.**—These may be started with Dahlias. In this case each strong growth that eventually forms must be detached with a portion of old roots connected with it. Plants obtained by thus roughly splitting up the old clumps are more effective when planted out than are masses of leaves springing from undivided clumps. Cannas seeds are extremely hard. Before sowing, soak them in a jar of water placed on the hot-water pipes or plunged in a hotbed till they have become soft and swollen to double their original size. All will not be fit to sow at one time. Merely soaking them for a given number of hours will not therefore answer. Place the swollen seeds singly in small pots of good soil, already plunged and warmed in a brisk hotbed, and they will soon complete germination.

**Miscellaneous Plants.**—Seeds of *Acacia lophantha* should be treated similarly to Cannas, and neat little plants may be obtained this spring. The seed of the Coral plant (*Erythrina crista-galli*) is equally hard, and this, too, should be soaked in fairly hot water till it has softened and swollen considerably, being then sown in previously warmed soil, and given the benefit of brisk bottom heat. *Grevillea robusta* seed does not require soaking, but should be sown in a pan, covered lightly with fine soil, and kept plunged in a hotbed till it germinates. The quality of the seed varies considerably, sometimes germinating quickly, at others either failing to do so, or refusing altogether. Plants raised last year would be the most effective in the flower garden.

#### PLANT HOUSES.

**Mignonette.**—Plants in 5-inch pots will have a tendency to grow weakly if not given abundance of air. Be careful, too, that the soil does not become dry. Thin the plants if they need it, half a dozen in each pot being ample, and pinch out any puny blooms that show. If the earliest plants have attained 4 or 5 inches in height pinch back or train the shoots close over the surface of the pot. Those plants that are flowering may have a little artificial manure applied to the surface of the soil.

**Fuchsias.**—Young plants that have been kept slowly moving may be placed into 5-inch pots. A compost of loam, leaf mould, manure, and sand will suit them. Place the plants in a temperature of 50° and supply each with a small upright stake. Old plants that have broken into growth may have the soil shaken from them and be repotted. A vinery that has been started will suit these plants well. Cuttings may be inserted as soon as they are ready, and another batch of old plants can be started in a vinery or Peach house that has just been closed.

**Lantanas.**—Plants that have enjoyed a good period of rest should be cut close back, leaving one or two eyes only of the last year's wood. Introduce the plants into warmth to break; in fact, the treatment advised for Fuchsias will suit them admirably.

**Cannas.**—When these are used in tropical or sub-tropical houses some roots may be started into growth. They should be placed in various sized pots according to requirements. Cannas will start very well in a vinery or any structure where the temperature ranges 45° to 50°, and may be stood amongst other plants in the forcing house if room can be found for them.

**Petunias.**—Bushy little plants of dwarf free flowering kinds in 3-inch pots should be placed into 5-inch pots and arranged close to the glass in a temperature of 50°. They must not be hurried; all that is needed at present is slow growth of a sturdy nature. Plants that are not needed may be pinched and allowed to break again before they are placed in the pots in which they are to flower. Plants kept for stock should be encouraged to grow and a batch of cuttings inserted in the course of a week or two.

**Heliotropes.**—Bushes or standards that have not been cut back will quickly come into flower if they can be placed in a growing temperature of 60°. White Lady is one of the best for this purpose.

Young plants in 3-inch pots place into others 5 inches in diameter, and if kept in a temperature of 55° will commence growth and make excellent decorative specimens in a short time. Plants not required for flowering early may be cut close back and started into growth in gentle warmth.

**Caladiums.**—The tubers of various kinds that have been stored away in a warm house where a fair share of moisture has been maintained will have started into growth. These should be shaken out of the old soil, and be either repotted in various size pots, according to demand, or placed in pans amongst light material until they have started and are ready for potting. We invariably pot and stand them for a time where they have been rested, but keep them syringed in order that the soil in which they are placed should not become dry. It is a good plan to plunge the pots amongst cocoa-nut fibre refuse, so that the soil does not dry too rapidly. Too much water in the early stages of growth will prove injurious. *C. argyrites* started in pans some time ago should be potted singly and pushed on for decorative purposes.

**Achimenes.**—Shake away the old soil and start the tubers in pans of light sandy material. These may be placed thickly in pans, especially if the main stock of decorative plants are to be raised from cuttings after they have started into growth. Plants that have been grown in baskets soak in tepid water and introduce into heat until they start into growth. All tubers that are placed in pots or pans, and introduced into heat, should be plunged where practicable to prevent having to water them too frequently.

**Tuberous Begonias.**—Shake a good batch of these from amongst the old soil, and place the tubers in leaf mould and sand in boxes until they start into growth. They soon start if they can be introduced into the forcing house where they can enjoy slight bottom heat. If the leaf mould is moderately moist a mere dewing daily with the syringe will be all the water they need until signs of growth are visible. Seed should be sown at once on the surface of fine soil made even in pans or pots. A sprinkling of sand may be placed on the surface before sowing. Water gently afterwards with a very fine rose can, but do not cover the seed with soil. Place a square of glass over the pans until the seed has germinated.

**Gloxinias.**—Seed may be sown on the same principle as advised for Begonias. If sown at this period the small plants produced are sufficiently advanced to bear shade without fear of damping before the sun gains too much power. Late plants are always useful, but for these seed should not be sown before the end of April.

## THE BEE-KEEPER

### APIARIAN NOTES.

#### SOME THINGS REVIEWED.

HONEY, as is well known, is a natural secretion gathered by bees from flowers and other parts of plants, and stored by them in hermetically sealed cells of wax. Neglect the sealing, and acetate fermentation quickly sets in; the hydrogen escaping and coming into contact with the oxygen forms a watery emulsion, thus hastening the process, whilst the attenuated ether which gives honey its flavour is rapidly dissipated.

To preserve honey as near its original state and flavour as possible the process of extracting and storing in hermetically sealed jars should be quickly performed, and without applying artificial heat, as that hastens the deterioration of honey. Some very beautiful chemical experiments can be made by the application of heat to honey in a vessel supplied with a nozzle, or without artificial heat if the atmosphere is extracted by an air pump, when the ether may be collected in a receiver.

Chemists appear to be unable to give us any reliable data to distinguish the difference between honey and sugar, so we are ahead of them with our simple experiments. There is seen a decided difference, and happily the detection is not difficult.

The over-extracting by the moderns has necessitated "ripeners," which quickly dissipates the essential oils that make honey so palatable and agreeable, leaving behind a residuum little better than molasses.

The best "ripeners" I believe in the market is the one invented by Mr. T. W. Cowan. It has a drying or evaporating metal surface of 30 feet, by which the honey is subjected to a high temperature and to the atmosphere at the same time. Young apiarians, ignorant of what has been done in the past, are prone to charge me with claiming credit for so-called modern "inventions" to which I am not entitled. Of course this is not true, and I lay no claim to Mr. Cowan's invention.

The beginner will observe that the volatile substances in honey are as essential to its good quality as salt and sugar are to the seasoning and preserving most of our food supplies, although used in small modicums or proportion to the bulk. He must, therefore

endeavour to have his samples of honey with all the virtues Nature gave them, because of the increasing imports of honey. According to the Americans' own showing, nearly 50 per cent. of their honey is adulterated (*vide* "Gleanings" for January 15th, 1893). British honey, to command the market, must not be reduced in quality by foolish actions of the bee-keeper.

#### SUGAR CLEANSING AND BEES DYING.

Professor Cook and others of America say that sugar undergoes a change after being fed to bees, and that it requires a "ferment" to prevent it "crystallising in the comb;" that "pollen" is the necessary ingredient, and unless that is supplied bees fed on syrup made from sugar will die during the winter.

The proposition is absurd. I have always contended that sugar stored by bees contracts a slight flavour, probably through the influence of the honey sac by an abstruse secreting organ or organs. I could quote hundreds of cases to fully disprove such assertions, but a few will suffice. It is a well known fact that our bees gathered no pollen to speak of after the middle of August. Owing to stress of weather it was late in October and even November before favourable weather enabled me to reduce my stock. The bees were given away, and all were fed with pure sugar syrup at a time when there was no pollen to be gathered. According to the American gentlemen these bees should have been all dead; but they are just the opposite, for all are healthy. The absence of pollen during the winter makes healthy bees. We do not remove it from the hives, as it ensures strong stocks and early swarms, but we feed with a few pounds of sugar in the autumn, and that is one cause of our stocks always being so healthy and easily wintered. I have not seen one speck of voided matter on or about any of my hives since shortly after I had them home from the Heather, and the winter has been both severe and protracted. If any ferment was added to honey or sugar the cells would burst, and the bees would die from dysentery.

The cause of sugar-fed bees dying in America is not due to what is stated above, but to cold, arising from the condensed damp upon the hives, and a ventilating floor and porous crown would have prevented the fatality.

#### STORING HONEY.

In the same number of "Gleanings" Mr. G. M. Doolittle asserts that the "field bee gives her load to a young bee, and this young bee carries it to the sections." This is mere hollow assertion. Until the young bee is five or six days old she is not capable of this work, and what if there be no young bees in the hive?

I have watched bees hundreds of times come direct from the fields and store their honey in the super comb. Moreover, I have repeatedly at the moors had bees which formed stocks made up from driven lots that could not be less than two months old and had no young bees. Yet on the resumption of work, after a prolonged idleness of three weeks, in five minutes after the bees began to come in I have on examination witnessed the newly gathered honey glistening in the cells; and similarly with others treated in the spring for foul brood, when honey began to be gathered from fruit blossoms. In a previous article the same author asserts that the maximum life of the honey bees is forty days.

#### VARIETIES OF BEES.

Mr. Benton has given a long dissertation on many varieties of bees to the North American Bee-keepers' Association. My own opinion is that too much weight is put upon what he says being as applicable to bees in this country as in their native land. I have often alluded to that; we can only test bees properly when side by side with others in this country. Mr. Benton makes a mistake when he states the purest Italian Alp bees are to found round the cities of Modena, Parma, and Venice; whereas those who have visited Italy and the Italian Alps have told us distinctly that the pure Italian Alp bee is only to be found in the Italian Alps, Switzerland, and not anywhere in Italy. He has, however, a good word to say on behalf of the Punic bees, describing them as being "excellent honey gatherers." In the same number, page 53, Mr. P. H. J. Baldensperger says, "I have obtained 120 lbs. of extracted honey in a honey flow of about twenty-eight days from the North Africans, but had to fly from their stings."

The savageness of bees under the management of people who are unacquainted with their temper cannot be accepted as a true criterion of their nature in a country where they are properly managed and understood by a truth-seeking and scientific people. The worst tempered bees I have had to deal with throughout the year were the original British bees. I have known them attack people, horses, and cattle a quarter of a mile from their apiary, and seldom could they be approached without being stung, and when at the Heather were perfect demons. Italians and Syrians were sometimes

worse, but their spitefulness lasted a short time only. Punics also showed at the Heather a little inclination to be spiteful, but they were not so bad as any of the three mentioned.

Strong attempts have been made from time to time by certain persons who had little or no practical experience with Punic bees to prejudice people against them, and I cannot free myself from thinking that the Editor of "Gleanings" has acted his part well, infallible as he strives to be. He has suppressed one or more favourable accounts of these bees, but gives full prominence to everything that is of a derogatory nature. He publishes a letter about Mr. Cowan, his portrait, and photograph of a manipulation with Punic bees, calculated in my opinion to impress people how spiteful they are, and adds that "Comment on the picture by us is unnecessary further than to note how the natives prepare for war." I entirely differ from the Editor's views. The hives and operators stand in the foreground against a pallisade which separates the apiary from some houses. The hives appear to be narrow frame hives, holding perhaps about half a dozen frames. One of the operators stands with a bellows and smoker, the other stands behind the hive, having in one hand a frame partly filled and held by a grip of some sort, while the other hand, bare, is grasping another frame. Why he has to grip one frame with tongs and is risking his bare hand with another is not easily understood. Neither the detached frame nor the hive itself shows many bees.

Mr. Thos. William Cowan has high eulogiums passed on him for four qualities, the last that he is the owner of 10,000 volumes of books. With one volume a day thirty years would be required to read them through. We had ample proof lately in these columns that Mr. Cowan did not know all that his journals contained. Does his library suggest the reason?

I will now turn my attention to the "Bee-keepers' Record" for February, 1893. Its pages teem with information and queries on the two queens in one hive system. The Editor persists in claiming the novelty of the plan for Mr. Wells. He says Mr. Wells "is entitled to the fullest credit," and goes on to say that it is not the doubling of swarms, as has been suggested by some critics of the two-queen system. The Wells' system is practically our system. It was described years ago in this Journal and practised by us for well nigh half a century. I now challenge the Editor and defy him to prove the Wells' system is "novel" or materially different from our plan of working two queens in one hive as I first gave it in these pages.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Brewin & Sons, Bawtry, Yorks.—*Garden and Flower Seeds.*  
H. Cannell & Sons, Swanley, Kent.—*Floral Guide for 1893.*  
Jones & Sons, Shrewsbury.—*Vegetable and Flower Seeds.*  
Henry Norton, Louth, Lincolnshire.—*Dwarf Roses.*

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

"**Monkey Tree**" (*A. A. P.*).—The very distinct Conifer, *Araucaria imbricata*, is commonly called the Monkey Puzzle, because of the difficulty the monkeys experience in climbing it, in consequence of the spiny appendages.

**Avenue Trees** (*J. H.*).—Of the trees in the list given on page 41, Horse Chestnut and Elm are best suited to the soil; and of evergreens, *Pinus austriaca* and *Picea nobilis*. In your first inquiry you did not state clearly the nature of the soil.

**Pruning Vines (A. A. B.).**—The Vines have made very good canes indeed, but if they had been ours we should have topped them when about half the length for strengthening the base and having bolder buds there. Having regard to the permanent well-being of the Vines we should cut the weaker down to the base of the rafters for encouraging strong growth next season, allowing them to bear no fruit; the strong canes we should shorten to within 18 inches or 2 feet from the base of the rafter, and allow two of the strongest laterals from each to carry a bunch of Grapes weighing 1 lb. to 1½ lb. each. If "quick returns" in fruit is the primary object the canes are strong enough to produce good bunches up a length 6 or 8 feet, but they would be weakened by the crop.

**Stimulants for Plants and Trees (A. T.).**—Neither nitrate of soda nor sulphate of ammonia affords anything like complete nutriment for plants and trees, and if long used alone, though they would incite rapid and possibly too rapid growth for a time, the ultimate results would be the reverse of satisfactory. When the soil contains ample mineral ingredients appropriate dressings of the salts named are beneficial. For plants in pots needing a push on, it would not be wise to commence with more than ¼ oz. of the salts to a gallon of water; but twice the quantity might be safely given to trees in borders that are in need of such stimulants. You do not possess a good grip of the nature, action, and effects of different kinds of manures, and should closely study the subject. The hotanical name of the plant from which cotton is commonly obtained is *Gossypium herbaceum*.

**Ribbon Borders (Anglo-Scot.).**—What are known as "ribbon borders" are those filled with lines of plants, each of a distinct colour. Such are scarcely desirable, or even possible, in your case, a mixture being more to the purpose. Tall Dahlias, alternating with either Sunflowers, Sweet Peas in patches, or Castor-Oil plants, would be the best for both borders; and in front of these, 2 feet or rather more away, plant *Fuchsia Riccartoni*, *Zea japonica*, and dwarf Dahlias of the Glare of the Garden type, many of the Pompon and single varieties, which can be raised either from seed or cuttings, also being of a suitable height. In the angles between these, only about 9 inches nearer the front, plant *Lovelies-bleeding*, miniature Sunflowers, tall Zinnias, African Marigolds, Princess Alice Stock, and Chrysanthemums coronarium and Dunnetti. A foot away plant a row of strong, early raised, and tall-growing *Antirrhinums* and *Pentstemons*, the tall Chrysanthemum-flowered Asters and French Marigolds also going well with these. Another foot nearer the front plant either East Lothian or early autumn-flowering Stocks, these being mixed if need be with Victoria Asters or other varieties of the same height. Dwarf Victoria, dwarf Chrysanthemum-flowered, and Empress Asters, *Godetias* Lady Albemarle, Duchess of Albany and Princess of Wales, and Ten-week Stocks could follow next, Tom Thumb Nasturtiums and Gaillardias being also suitable for this row. For the edging a line of dwarf blue *Lobelias* would be better than Golden Pyrethrum, or the two might be mixed. If the plants in all but the front and three back rows were planted in groups of threes, the borders would be better filled, and stiff lines be avoided. The selection given would commence flowering fairly early in the summer, and be gay till severe frosts intervene.

**Planting Fruit Trees and Roses in Spring (B. D. K.).**—Last year, about this time or a little later, a gentleman who had planted 2 acres of land with fruit trees just before the frost, asked our advice about completing the work (other 2 acres) then, or deferring it till the autumn. We advised him to order trees at once, and tell his nurseryman they would only be accepted on condition that they arrived in a moist state, root and branch. If the ground was in a friable condition when our correspondent received the trees, he was advised to cut off the end of every broken root and plant carefully at once. If the weather was not favourable for planting, he was advised to place the trees in a trench, well covering the roots with soil, and scatter some litter over the slanting tops to shield them from the sun, then seize the first favourable day for planting. Our advice was followed, the long young branches cut back, two thirds of their length being removed. The result was that most of these trees made distinctly better growth than those that were planted in winter (not in the autumn) just prior to the severe frost, and their owner is now delighted with their condition. We have Roses yet to plant, and shall not hesitate in planting. The chief factors for insuring good growth are (1) friable soil; (2) roots not dried by exposure, and all broken ends pruned smooth; (3) shortening the branches freely to reduce the evaporating surface. We shall not mulch with manure now, as we want every possible degree of sun heat to warm the soil and stimulate the emission of fresh roots. We may possibly mulch as summer approaches to keep the ground moist, and promote fibrous root activity near the surface.

**Asters for Cutting (A. E.).**—There is nothing to prevent one so intelligent and energetic as yourself from succeeding well with Asters, and you ought to send some to Spitalfields as well as Covent Garden Market, the commoner bunching flowers sometimes selling well at the former place. The varieties we can recommend are either Harbinger or Pride of the Market; as a good early white, Queen of the Market, colours mixed, also being a freely flowering strain. The new White Comet is particularly good and sells readily, the flowers resembling Japanese Chrysanthemums, and there is also a blue form of Comet. Varieties with incurved blooms seem to take best in the market, and you cannot do better than grow Truffaut's Pæony-flowered Perfection, colours

various, extensively. There is also a constant demand for white flowers, and you will do well, therefore, to grow a good sized bed of Dwarf White Pæony-flowered Perfection. You failed to state what convenience you have for raising the plants. Probably you have a frame or two. If so form a slight hotbed towards the end of March. Set the frame on this partly filled with some of the shortest heating material, and on this place not less than 4 inches of the best fine soil available. Water this if at all dry; sow the Aster seed thinly broadcast, and cover with a little fine soil. Avoid unduly coddling the seedlings, and gradually expose them to all weathers. If not at all crowded, fairly sturdy plants will result, and these should be moved to where they are to grow when about 3 inches high. If raised thickly, the plants will have to be temporarily pricked out 3 inches apart each way in beds in a sheltered position, and protected with benders and mats for a time. Failing glazed lights, form the shallow hotbed, drive stakes into the corners and along the sides, and with 9-inch or rather deeper boards enclose the bed of soil sowing seed as previously advised. Protect closely with mats or carpets till the seedlings appear, and subsequently during cold nights only. A number of sturdy plants may be raised in that way, and the bed of manure be available either for a Vegetable Marrow bed or for mulching other crops. Asters delight in a fairly rich well-worked soil, failing quickly on poor non-retentive ground. Form beds 6 feet wide to hold five rows of plants, alleys 1 foot wide between them being sufficient. All ought to be planted by the end of May, and from 10 inches to 12 inches apart in the rows. This work is best done in showery weather. Do not wait long for that, however, but give occasional waterings till the plants are growing strongly, when, if possible, a mulching of short partially decayed not fresh manure should be given. The taller growers, notably the Pæony-flowered varieties, ought to be lightly staked, Birch or Hazel spray answering well.

**Sweet Peas for Bunching (A Lady).**—If Sweet Peas are sown on rich deeply dug ground, and early mulched with strawy manure, they will yield flowers profusely and continuously till cut down by frosts. Keeping the flowers closely cut favours this continuous production, the plants being liable to cease flowering directly a heavy crop of seed pods set upon them. Eckford's new varieties quite eclipse the older forms, but are somewhat expensive, or at any rate you might think them so if bought in separate colours. Many good forms are included in packets of Eckford's mixture, and in addition to these you ought also to have either Princess Beatrice or Mrs. Gladstone separately, the delicate pink colour of these varieties being much appreciated by ladies. Carmine Invincible is likewise a taking colour. Also sow at least a pint of the common white form. Very choice varieties are sold in small packets, and in order to lose none of the seeds it is a good plan to sow them in 4-inch pots, five or six in each, placing these in gentle heat, eventually hardening off and planting where they are to flower before they become badly root-bound. This not being possible in your case, be content to sow the common varieties where the plants are to grow and flower, as early in February as the ground can be got into a free-working finely divided state. The choice varieties will not decay in the ground if sown during the first fortnight in March, always providing the ground is not in a cold wet state. Sweet Peas might be sown and grown in patches of about six plants 5 feet apart through the centres of the beds of Asters, with little or no detriment to the latter, and they branch and flower grandly when thus kept in isolated groups. If preferred you could arrange continuous rows 9 feet apart, and fill in 6 feet of the space between with Asters. Anyway, there must be no crowding of the Peas, or they will fail to branch strongly, and not be continuous flowering accordingly. If the seed is sown in drills a pint of seed ought to be sufficient for rows equal to a length of 100 feet. Both rows and patches should be supported, but not too tightly, by good hazel stakes, or the best substitute for the same, and in dry weather occasional soakings with pond, or other soft water, varied by sewage water or liquid manure, may well be given, but if you have a deep strong soil these are not absolutely necessary.

**Orchard and Kitchen Garden (J. H. E. B. H.).**—The old fruit trees may have the heads encumbered with weak and dead wood, and would be improved by a judicious thinning of the crowded parts and cutting out of the old wood. This should be attended to without delay, performing the operation carefully, and with judgment, so as to open out the heads for the admission of air and light. Over-thinning is not desirable, but a moderate manipulation so as to admit of a person between the branches, and the spurs a good hand-breadth apart, is attended with good results. The grass would be best closely eaten off by sheep, supplied with hay, Swedes, Oats, or oilcake, and on different parts, so as to manure the ground equally. The droppings and urine, combined with the treading, would have a beneficial effect on the soil, not only in manuring it but in the destruction of larvæ. If the trees are infested with moss and lichen they should be dusted whilst damp with quicklime, placing the lime in a coarse bag attached to the end of a pole, and a person with a ladder would readily distribute the lime over the trees on a still day. The ground may be dressed with Thomas' phosphate powder 7 lbs., and kainit 2 lbs., mixed, per rod (30½ square yards) after the grass has been eaten off by sheep. If the sheep are not available the orchard should be well manured after the trees have been pruned, forty cartloads of stable or farmyard manure not being too much per acre for neglected orchards, but heavy dressings are often more prejudicial than otherwise, and judgment must be exercised. You will find particulars for making an Asparagus bed in the "Garden Manual," which will soon be republished, and may be had from this

THE "shooting" season, the commencement of which is in August, brings to many gardeners a press of work and worry. Work may be overcome, and in general is not harmful. Worry, on the other hand, is in every respect always bad, and the only means of escaping it lies in being well prepared for seasons of increased requirements. Though gardeners of lengthened experience know what they have to expect, and how to provide so as to meet with equanimity seasons of pressure, others may not be so well equipped. For such of the latter class as feel they need a little assistance I trust what follows may be helpful. There are at least two matters of importance which, if thoroughly taken in hand at the beginning of the season, will have the effect of facilitating the work considerably. The one is to map out what is intended to be done, to allocate as it were to each crop its place. It is not likely that the plans will be quite realised, for the material is of a changing nature, but they will be near to realisation. The other matter is very much of the same nature. It is this: Where garden produce is required in bulk at a particular season the method to pursue is to concentrate one's energies and labour on a few good things. To know what you are doing, and grow only first-rate things, are, I think, matters of great importance. Another thing worth noting is the large number of gardens which are kept simply as productive agencies for supplying certain fruits, flowers, and vegetables, little thought being given to keeping the grounds in a proper condition. In all such cases abundance of a few reliable kinds is again the key which opens the way out of the difficulty.

I shall refer first, and very briefly, to vegetables; and as Potatoes are being discussed I need say nothing of them. Of equal importance with the Potato is the Pea crop. To the inexperienced grower Peas are, in the matter of variety, bewildering. It may be said with truth in regard to both, that a large number of really good varieties may be selected. I know a gardener in a high position whose one and only Pea for early, midseason, and late crop alike was, for years, Veitch's Perfection. This is rather a choice selection; but I believe few gardeners who have grown this Pea will ever care to pass an autumn without its aid. Three sowings of this, at intervals of ten days, in May, with another in early June, and a good breadth of Ne Plus Ultra for a late supply, will yield an abundance of Peas during the autumn. The tips of the growth of the latter variety ought to be removed when they attain to a height suitable for reaching with ease. For ordinary purposes Dr. McLean and Omega are useful. Dwarf kidney Beans will be well secured if either Negro, Canadian Wonder, or Ne Plus Ultra is grown. The former will require to be sown in the first week of May, and either of the three a month afterwards. For Cauliflowers, either Early Erfurt or Magnum Bonum, sown out of doors in March will supply the crop after the earlier kinds are past. Then Suttons' King, sown a week or two later, will form a succession till the time that Autumn Giant, sown in March, comes in. I have seen Stadtholder fairly good till November, but the best of any at that date was Drummond's Late Frankfort.

Lettuces are becoming plentiful, but few can out-rival the ancient Hick's Hardy Cos. There are some larger in size, but not one which turns in better, or is of superior quality when properly grown. Of Cabbage Lettuces there are some very good varieties.

I do not grow many of these, as they generally lack crispness. Spinach is not, perhaps, so much wanted in the autumn as at other times; but it has to be grown. The two best varieties are, I think, Viroflay and Paresseux de Catillon. Very much depends on the care taken with the sowing. Plenty of water in the drills when sowing has a wonderfully good effect. Of Turnips, no better autumn sort than Snowball need be grown. A vegetable which everyone ought to have a couple of sowings of is the London Colewort. The time to sow seed of this is in May, and again in June. If the plants resulting from the first sowing are merely thinned out and not transplanted useful little heads for the dining room are produced early in the season. Express is a good autumn Cabbage, and the seed should be sown in March or April. Brussels Sprouts are sometimes lightly spoken of, but they are useful. The two varieties I prefer are Paragon and Paris Market. Guerande Carrot is quite first-rate, and St. Valery, which is longer, is also good. For ordinary purposes Cranston's Excelsior Onion appears to hold its own for autumn use.

Flowers for cutting are most important. Very often no real attempt is made to meet the demand, as is done in the case of vegetables. But it is wise to do so, and in addition to those grown in borders it is imperative that a distinct supply for cut purposes be also cultivated. In this case the object in view must be considered. The flowers of autumn are numerous; a rigid selection is most likely to be best. There are some flowers which I like to have, as for example Gladioli, by the hundred. In the same way I like to have plenty of the old Cactus Dahlias, Carnations, Sweet Peas, Mignonette, and Michaelmas Daisies.

A supply of good flowers may be secured from annuals alone. Mignonette sown in March or the beginning of April is most useful. Such esteemed varieties as Cloth of Gold, Machel, and Garaway's White should be grown. Sweet Peas also ought to be well cultivated. Really indispensable are such varieties as Countess of Radnor, Lady Penzance, Mr. Eckford, Mrs. Gladstone, Her Majesty, Orange Prince, Mrs. Sankey, Firefly, and Captain of the Blues. The Godetias are very choice for cutting. Sow about the end of March, and give each plant a foot or 18 inches square superficies to cover. The white annual Mallow is fairly good and worth attention. Salpiglossis are really charming. They can be used for the most select purposes. The plants are best raised early in heat and transplanted into boxes to develop strength. A flower I seldom see, but which I like very much, is the single Aster. Everybody grows double Asters, quilled, flat, incurved, but the much more pretty singles nobody appears to pay any attention to. Of other Asters the quilled is very suitable, and I like The Comet. Aster seeds are best sown in April and the plants brought on slowly. They revel in a light rich soil. Zinnias, especially the single form, are good. Of other annuals the common yellow Cornflower ought not to be overlooked, nor Iceland Poppies, of which I had a double strain last year. A packet of mixed annual Chrysanthemums will secure useful flowers for cutting.

Plants of a less short-lived nature are no doubt led by the Carnation. Good Carnations are plentiful, but for cutting the Clove-scented are indispensable, the old red Clove being most useful. Mrs. R. Hole, Germania, and Raby Castle must be also grown. Gladioli are easy to grow, and take but little space. I plant the bulbs about three or four to the foot, three rows close together, and a wider space as a path between every third and fourth row, and find them do admirably. Really good sorts, such as Phoenix, Dalila, Sultana, Meyerbeer, and many others are inexpensive. Very useful also are the various Montbretias, crocosmaeflora being the best for cutting. Etoile de Feu and Gerbe d'Or I also like. Hyacinthus candicans is very good for cutting. It is now cheap, and may be grown extensively. It is easy to raise from seeds. Sow in rows in spring, to remain for two years, and transplant the third and fourth year. Tiger Lilies and Phloxes are fairly useful, but ought not to be employed for any other than common purposes.

By cutting, and at once placing in water, I have found Pentstemons very serviceable.

Of Dahlias no doubt *Juarezii* is the best. Other good varieties are Henry Freeman, white; Honoria, yellow; General Gordon, salmon; Robert Maher, Panthea, and for some purposes Glare of the Garden. I always cultivate a few of the single variety Chilwell Beauty for cutting. In order to have these in flower early the old tubers ought to be planted, and not, as is generally the case, young plants raised from cuttings.—R. P. B.

### PROPAGATING BEDDING PLANTS.

DURING the next three months millions of plants of various descriptions will be propagated in the private gardens of this country. In some instances the work will be carried out under adverse circumstances; in others the labour-saving appliances of modern times will render it simple, easy, and highly interesting. No matter what difficulties have to be encountered the energetic gardener generally overcomes them, and when the time for bedding-out arrives there is frequently not much to choose between the plants which have been raised and forwarded under difficulties and those produced under the most favourable conditions; but there is a vast amount of difference between the attention required in the two instances. In the former a great amount of wasted force has been expended to produce results which in the latter are accomplished with ease. This being so it is obvious that a few pounds expended in the erection of a suitable propagating house or pit, having at command plenty of bottom and top heat, is money well spent. When, however, this convenience does not exist it is a great advantage to know the various conditions under which different plants may be rooted with certainty, for it is a curious fact that propagators who are equally successful sometimes adopt totally different methods of procedure, and the man who is thoroughly conversant with these opposite methods will generally be able to successfully adopt one of them.

The first step to be taken is to see that all plants which are to be rooted in well heated structures receive a fair amount of heat for a couple of weeks previous to the insertion of the cuttings. By taking this course the sap is incited into activity, and the sap vessels being fully expanded are in the right condition to ensure the speedy emission of roots. Many causes of failure might be traced to the non-observance of this practice, which is generally easy enough to carry out, because a large number of bedding plants are grown in vineries and other fruit houses, one or more of which are started at the beginning of January. If the earliest batches of plants to be propagated from are arranged in this early started house the first cuttings will be ready a few weeks after, and others will then be quickly produced. In cases where neither of the fruit houses is pushed on early the work of propagating may with advantage be correspondingly delayed, unless other houses or pits can be devoted to the purpose. Another point which deserves more attention than it receives is to allow the cuttings to become strong before they are taken from the parent plant, for nothing is gained—indeed, much is lost—by beginning too soon. Weak cuttings produce poor plants; and, moreover, the parent plant is increased in vigour by additional growth. The next batch of cuttings come quicker, and are more robust, when this course is followed than when the opposite practice is adopted.

#### PELARGONIUMS.

Given a temperature ranging between 60° and 70° few plants are more easily rooted than Pelargoniums. The soil I prefer for the majority of cuttings is old potting soil which has lain for a few days on the top of a boiler at work or against a chimney stack. If turned a few times while in these positions it becomes thoroughly sweetened, insects are dispersed, and the requisite warmth is also obtained. If a heap of such material is sifted through a half-inch sieve, with a little leaf soil, crock dust, or sharp sand added, it can afterwards be varied to suit the special requirements of various plants. Cocoa-nut fibre refuse is an excellent substitute for the leaf soil where that is not easily obtainable. This mixture will be found especially suitable for Pelargonium cuttings, as they are generally somewhat soft, and are less liable to decay at the base when inserted in rather poor soil.

Where the space can be spared the best of all methods is to insert each cutting—after having made a clean slanting cut just under the joint—in a small 60-pot. There is no possibility of overcrowding when this plan is followed, the growth is firm and sturdy from the start, and no further potting is required. One crock, covered with moss or rough leaf soil, is all the drainage necessary. Open stages placed on the hot-water pipes in vineries

or shelves near the glass are excellent positions in which to stand the pots. Well heated pits with a stage formed of boards, over which a little cocoa-nut fibre refuse or sifted coal ashes have been placed, afford an exceptionally good position for them. Cuttings of the Tricolor and Golden Bronze types should, if possible, be given such a position; they can then be kept quite close and given the exact treatment required.

If space cannot be afforded to place each cutting in a separate pot, boxes should be used. If made about 2 feet in length, 10 inches wide, and 2½ inches deep, these will afford room for from forty to fifty cuttings, according to their size. Half an inch of cinders or broken crocks, covered with a layer of rough leaf soil or moss, supplies sufficient drainage and leaves ample room for the soil, which ought to be pressed moderately firm with a board made to fit easily into the box. This is a very convenient method, as large numbers of cuttings can be raised in a limited space; but of course they should be placed into pots as soon as the cuttings are well rooted, by which time higher temperatures prevail in the majority of glass structures. When only a few cuttings of many varieties require to be inserted 6-inch pots answer admirably. These will accommodate nine cuttings, and are of the right size for standing on hot-water pipes and in dry corners where many things do not flourish, but Pelargoniums root quickly. In all cases the soil should be surfaced with sand, and the cuttings, when inserted, receive a good watering. The subject will be resumed.—D. W.

### LILIES VERSUS ROSES.

I SUPPOSE that for one person that cultivates Lilies 500 cultivate Roses. In all summer horticultural shows Roses occupy the first place, but Lilies take a back seat. There are special Rose exhibitions and a National Rose Society; the modest Lily hangs its head in obscurity. Why is this? Is the Lily inferior to the Rose? I think not. For purity of colour no Rose can touch the Lily; for fragrance, in my opinion (a matter of individual taste), no Rose can equal in delicacy the perfume of the speciosum or longiflorum group, including *L. Browni*, or in strength that of *L. auratum*. For lasting as a cut bloom, whether as regards colour or fragrance, the Lily will keep good during a week; the Rose is gone in twenty-four hours. Under glass one may have Lilies all the year round in bloom; not so Roses. For grace and stateliness, granted equal excellence of growth and cultivation to both, there is no comparison between any Rose bush and *L. auratum*, longiflorum, or speciosum. Whence, then, the difference in popular cultivation? I suppose that the Lily is generally held to be far more difficult to grow than the Rose; that after flowering the bulb often perishes, that renewals are costly and troublesome; but surely this is because the cultivation of the one is less understood than that of the other. A deciduous bush renews yearly only shoots and flowers; the Lily, in addition, has to make a bulb, on the size and soundness of which its future life depends; hence a greater demand that its environment should be suitable and its requirements understood by the cultivator.

Now, as regards environments. It is true many soils do not suit Lilies; they require moisture and a fair amount of sunshine; light sandy soils therefore do not suit, neither do heavy cold clays. Given partial shade, abundant moisture combined with drainage, and a fairly open retentive soil, Lilies will do well. If you wish to see them well grown go to Kew and admire the beds there. Now this environment is more restricted than that required by the Rose, and it cannot be found in many gardens, but it can be had artificially. In my town garden of 20 feet by 50 feet I grow in pots magnificent groups of longiflorum, speciosum, and other Lilies; but I take care that the pots are large enough, and never use less than a 10-inch pot for a single bulb. Large bulbs or several bulbs together require a pot up to 15 or 18 inches wide. Sankey's pots are deeper, and therefore give more room to the requirements of the roots. The soil I use is a fibrous loam with some sand and peat to keep it open, and the plants get sunshine about half the day. They are kept well watered, this being most important. If not plunged they get soaked every evening at sunset; if plunged, every other day; during growth some Clay's fertiliser is also added. I have magnificent growth, splendidly coloured, and fine blooms, and grand bulbs for the next year, and this in a town garden. If one can do this so easily, why not others? A grand pot of *L. longiflorum* or speciosum in flower is a graceful, beautiful sight, well worth a little trouble. Green fly does not infest my Lilies like it does my Roses, and no caterpillar eats the buds.

I finish, therefore, by again asking, If Roses why not also Lilies? I could add much more in favour of Lilies, but one point more should be mentioned. A Lily coming in flower in the open garden may be taken up with care for its roots, potted, and well

watered; it will bloom and complete growth without injury. I never heard of a Rose bush treated thus successfully; but I have often been asked incredulously, "Can these Lilies really be grown out of doors?"—ALEXANDER WALLACE, M.D., *Colchester*.

#### CATTLEYA PERCIVALIANA.

THIS is a grand and very free winter flowering Cattleya. Out of a small consignment had a couple of years ago one is a long way ahead of the others, which have all flowered. The plant in question bloomed in January, 1892, and again in the corresponding month of this year, and is still flowering. The petals and sepals are the same colour, but much larger than are those on the other plants, while the lip is also larger and the colouring very rich—rosy-pink and purple, and edged with white shaded with pink, the throat being a deep orange with dark base, and fringe.

This Cattleya is a good grower, and, together with the several varieties of *C. Gaskelliana* and *C. Trianae*, help to make the house gay during the present time of year. Plants potted firmly and well up in the pots in a mixture of sound fibrous peat and sphagnum moss, and good drainage being afforded, make a free growth when given plenty of heat and atmospheric moisture during the summer months. The material about the roots should be kept uniformly moist during that period, and afterwards well maturing the growth being all that is necessary from a cultural point of view to achieve satisfactory results in flowering.—H. W. W.

#### PHAIUS ROSEUS.

THIS very distinct Phaius was collected by the Right Hon. the Earl of Scarborough. The habitat, says the *Kew Bulletin*, is not absolutely known, but it is supposed to be West Tropical Africa. It flowered in Lord Scarborough's collection in December last, and was sent to Kew for determination. The flowers are of a delicate light rose shade, the lip somewhat marbled with white spots, the disc with a white hairy fleshy keel and a minute tooth at the apex, and the spur deep yellow. In fading the flowers pass to a light orange-buff shade. It would be the second species discovered in Western Africa.

#### PHOLIDOTA LUGARDI.

This species is allied to *P. articulata*, *Lindl.*, but is altogether a more robust plant, more erect in habit, and larger in all its parts. The sepals and petals are semi-pellucid white, and the sac of the lip pale flesh-coloured, the keels unequal and buff-coloured, and the base of the auricles deep yellow. It flowered in the collection of Sir John Kirk of Wavertree, Sevenoaks, in June, 1890, when he forwarded it to Kew for determination, together with a living plant, which has since flowered. It is one of a large collection made by Captain Lugard in Western Burma—(*Kew Bulletin*).

#### PHAIUS TUBERCULOSUS.

A SPECIMEN of this rare and beautiful Phaius is now flowering in the warm Orchid house at Kew. Unfortunately this species has proved very intractable under cultivation, and, as most growers experience great difficulty in preserving it in even moderate health, a well flowered plant may be looked upon as a triumph for the successful cultivator. The Kew plants are grown on Tree Fern stems, with living sphagnum about the rhizomes, in a hot, moist, shady corner of a propagating pit.

*P. tuberosus* is a comparatively recent introduction. The first plants brought to this country from Madagascar were sold at Stevens' Rooms in 1881, and realised high prices. It first flowered in England in the same year in the collection of Sir Trevor Lawrence. Since then many Orchid growers have tried to overcome the difficulties of its cultivation, most of them with but indifferent success. In general appearance this species differs considerably from its allies. It has a creeping stem from which spring the slender pseudo-bulbs with narrow leaves 6 to 9 inches in length. The erect spikes bear from four to eight flowers about 2½ inches in diameter. The beauty of the flower lies chiefly in the lip, which is three-lobed and of considerable size. The middle lobe is white tinged with rosy purple, the lateral lobes are larger and curve

inwards, colour dull crimson, freely veined and spotted with golden yellow. It is undoubtedly the finest species yet introduced.—A. B.

#### CALANTHE GIGAS

The number of bold and striking *Calanthes* is not great, consequently there is little fear of so fine a hybrid as *C. gigas* passing unnoticed, and it is not surprising that when exhibited by Messrs. Veitch & Sons at the Drill Hall on January 17th it should have received marked attention. By common consent it took rank as a great acquisition, and a first-class certificate was awarded to it by the Orchid Committee. The plant is the result of a cross between *C. Sanderiana gigantea* and *C. vestita grandiflora*. It is bold, vigorous, and effective, the stout spike containing numerous

FIG. 24.—CALANTHE GIGAS.

handsome flowers, the sepals and petals of which are ivory white, and the lip rich rose. Fig. 24 represents it.

#### DISCUSSION ON APPLES.

##### UNCTUOUS APPLES.

SOME time ago criticisms appeared on my use of the term "unctuous." I think it is correct. It means of the nature and quality of an unguent—oily or greasy to the feel. The unguent on Apples is an exudation slightly sweet and adhesive. My object in touching upon the subject again, however, is not to give information, but to obtain it. There are both fruits and vegetables which produce wax upon their surface. Wax is a fat produced from sugar or its relatives. In that case it would be as proper to call the exudations "unctuous" as it would "glutinous." There is, perhaps, no difference in the mechanical or the chemical change of honey or sugar into wax by the bee from that of the fruit or vegetable, or of any animal that produces fat. The chemist

changes starch and other cellular substances into sugar, but I believe the changing of these substances into wax is not yet discovered. How is the wax on fruit produced?—by oxygen externally, or in combination with internal acid? Let those who can enlighten us on the subject do so.—W. T.

DR. HARVEY.

WILL Mr. Chinnery, if he has any fruits of satisfactory form, kindly send half a dozen of this Apple to the next meeting of the Fruit Committee of the Royal Horticultural Society, Drill Hall, Westminster, and also if he has some of Wormsley Pippin? It would be very useful if the doubts as to the identity of these and Waltham Abbey Seedling could be cleared away. It would then, if found identical, be a question as to which appellation was the oldest. If Mr. Chinnery has not samples of the kinds named perhaps some other readers may have them. It was long since shown that there was no connection between Golden Noble and Waltham Abbey Seedling.—A. D.

ROYAL PEARMAIN.

THIS is an excellent late dessert variety; fruits about the size of those of King of the Pippins, shape of Scarlet Incomparable, but has an open eye, like that of Blenheim Pippin. It does remarkably well at Dropmore, and Mr. Herrin speaks in warm terms concerning it as his very best late dessert variety. I have just tasted a fruit, and find that it has very crisp, juicy, and well-flavoured flesh. So far as form is concerned it is really a handsome Apple, and seems to be well worthy of extended cultivation.—A. D.

HOLLANDBURY.

I CAN fully endorse what has been said in favour of the above variety. Not only is it a handsome and good Apple, but the tree is also a sure cropper. An old tree in the gardens under my charge bears heavy crops of beautiful fruit. The soil in which it is growing is very heavy, resting on clay, in a low situation. If I were planting Apple trees extensively I should certainly include a good number of this variety.—R. MORSE.

WALTHAM ABBEY SEEDLING.

WITH me this variety has been the most obstinate of all in producing a crop of fruit until this year. The tree, a freely grown bush, has been planted a dozen years, and it has been root-pruned twice during that time. Our heavy soil seems to suit its growth admirably; there is not the slightest trace of canker, the wood is a good colour, and the foliage perfect in health. Last year it produced a full crop of handsome fruit, and the prospect for this year's blossom is good. My experience suggests that, good as this Apple is for cooking, the tree is too slow in bearing to be recommended for heavy soil if a quick return in fruit is desired.—E. M.

RINGER.

IN a cottage garden a large tree, which cannot be less than forty years old, of this variety bears abundantly almost every year. This is a grand variety for use during August, September, and October. For cooking purposes this Apple is equal to Lord Suffield or any of the Codlin type. In addition to the fruit consumed and given away from this one tree last year, the remainder were sold to a higgler for 23s.—not a bad return from a tree which receives nothing in the way of cultivation. Apparently the tree has not been pruned since it was planted.—S. P.

A COOKING TEST FOR QUALITY.

THE interesting and instructive notes on Apples in the *Journal of Horticulture* reminds me of a trial of Apples in a cooked state. About 100 varieties were tried, with the following result:—First quality.—Rich, crisp, juicy, and briskly acid, some having a distinct perfumed aroma. Bismarck, The Queen, Schoolmaster, Stirling Castle, Stone's or Loddington, and New Northern Greening. Second, very good.—Tender, juicy, sugary, and pleasantly sub-acid, some briskly acid. Warner's King, Peasgood's Nonesuch, Cox's Pomona, Hawthornden, Small's Admirable, Prince Albert, Omar Pasha, Striped Beefing, Old Winter Pearmain, Holland Pippin, Tower of Glamis, Ecklinville Seedling, Cellini, Beauty of Kent, Gravenstein, Blenheim Orange, Bramley's Seedling, Rymer, and Normanton Wonder. Third group.—The Codlin type, well known and invaluable for early use, the best being Keswick Codlin, Lord Suffield, Pott's Seedling, Domino, and Golden Spire. Fourth group.—More or less unsatisfactory in flavour. The Crab, Cockpit, Betty Geeson, Lord Grosvenor, Annie Elizabeth, Lord Derby, and Sturmer Pippin. The indifferently flavoured Apples are mostly greenish-fleshed varieties. The same remark applies to many yellowish-fleshed sorts, but there are exceptions.—W. B., *Lincoln*.

## SEASONABLE HINTS ON FLORISTS' FLOWERS.

I HAVE always regarded, whether rightly or wrongly, the month of January as the most trying month in the year, for what we older florists used to consider florist flowers pure and simple. Of late years many have been classed by some writers under that term. It is not on account of the great cold, although it is probably the coldest month of the year, but because in such flowers as I write of which are wintered in pots in frames there is so much fear of damp, as in severe weather the flowers have to be kept close, and hence damp is apt to injure the plants; therefore, although we must not halloo yet, for we are not out of the wood, yet when the month of January is past the greater portion

of our winter troubles are over. Let me here remind those who read these notes that I do not write from the exhibitor's or large grower's point of view. My selections are small, and I grow them for home pleasure, not for display on the exhibition table.

AURICULAS.—I generally find that, provided the frames or pits are well protected from frost, a hard winter suits these plants; indeed, frost will not kill them even though the soil be thoroughly hard, but it is apt to crumple the blooms and cause them to come out of character; but when protected they remain without water for so long that they are preserved from damping. I remember old George Lightbody once telling me that he never gave his plants any water from November to the end of February, but this was in the far north, at Falkirk. In looking over mine I find the winter losses to be fewer than usual; indeed, the only plant which I have to mourn the loss of is Booth's Freedom, an old flower and one always difficult to keep. The plants ought to be gone over thoroughly and all dead and decaying leaves removed, and if there is any sign of aphid the plants should be brushed with a camel's-hair pencil, or the frames or pits may have a slight smoking of tobacco paper. Woolly aphid, which used to have such terrors for us, is now regarded with much less dread; indeed, I take no trouble about it. If it appears at the neck of the plant I remove it, but in no other way at this time of the year does it disturb my peace of mind. The surface of the soil in the pots should be gently stirred with a blunt stick; and as always great cleanliness should be observed water will have to be given more frequently as the month advances, and air at all times when the weather permits it. As I grow my small collection in a pit ventilation is much more easy than in frames.

CARNATIONS AND PICOTEES.—To those who grow these flowers in pots this will be a busy month, for all ought to be finished before the month is out. There is no other way in which these plants can be so successfully grown for exhibition. The compost has of course been thoroughly prepared long ago, and potting is the only thing to be done. When the plants are placed in the pots a small stake about a foot high should be placed to them to give way by-and-by to the permanent blooming stakes. It is best, where possible, to place the potted plants in some place where they can be sheltered from the parching winds and heavy rains. As I do not grow them in pots but only in a bed in the open my plants which are to fill my beds are now in small pots in a frame. On looking over them I find them strong and healthy, and free from that woeful enemy spot. I have long since given up the idea of leaving them out in the beds all the winter. Some kinds will stand it, but unfortunately you cannot tell which they are, and thus I have seen in a severe winter a clean sweep made of the old Clove, while Mrs. Reynolds Hole has stood the two last severe winters in my border uninjured. It is therefore wiser, as I think, to keep even the border varieties in pots. They must now be kept clean, and all decayed or decaying leaves taken off, and the pots kept clear of weeds. Should green fly make its appearance it should either be brushed off with a camel's-hair brush, or the frames should have a smoking of tobacco paper.

GLADIOLUS.—I have a sorry tale to tell of these, into which I may enter more at length at some other time; but never but once have I had such losses, and when I say that nearly two-thirds of my collection is clean gone, it will be seen how heavy the blow has been. The roots should be carefully looked over, and although I do not plant as yet, there are some kinds which make considerable shoots even on the shelves where they are placed. Shakespeare, Adolphe Brongniart, and others are apt to do this. They should be potted in small pots in strong loam, so that when they are turned out the roots will not be displaced. The frosts which we have had ought to have mellowed the ground for planting.

PANSIES.—These are always difficult plants to manage in this southern latitude, and although the Fancies are much more robust than the old Show varieties, I find them very likely to go off during the winter, especially when, as during the past two months, the frames have to be kept tolerably close; they then damp off, and I have lost a considerable proportion of my small collection during the past winter. I only grow them in pots, and at this time place them in larger pots than they have been wintered in; they are then replaced in the frame, given as much air as possible, and watered when the weather permits it.

ROSES.—I do not think it necessary to enter upon any details about these flowers, a space being devoted in this journal especially to them, nor have I as yet ascertained for myself what the effects of the winter have been. I saw my neighbour, Mr. Foster (the inventor of the patent tube, &c.), and he told me that while his old plants were all safe, he was afraid that he had lost five-sixths of his buds. I hope this is not the general tale. I am not myself a *Buddhist*, and so know nothing about such plants. My own plants seem, even the Teas, to have escaped tolerably well.

RANUNCULUS.—The time for planting these has now arrived, and I am truly surprised at the disfavour, or rather, I should say, neglect into which they have fallen. I know they are troublesome, but a lover of the garden does not, as a rule, mind that. I believe the trouble was made greater in former times by the minute directions given for the preparation of the beds and their general culture. I am ready to grant that when these directions are attended to there may be a greater certainty in their culture, but I am quite sure they are not in many cases absolutely necessary. Where there is a good garden soil, and the situation not too hot, the soil rather moist than dry, but free from stagnant water, they can be grown with success, and now is the time for planting them. The bed, for they are worthy of a place to themselves, should be flat, about 4 feet wide. When planting drills should

be drawn not more than 1½ inch deep, a little sharp sand placed on the bottom, and the tubers pressed firmly in. The best distance is about 5 inches, and the rows should be about 4 inches apart, and care should be taken to get rid of worms as far as possible, as they are very apt to displace the tubers. When I used to grow them under name this was a great annoyance, as the roots used to be drawn up, and one could not tell where they belonged to; indeed this was my chief reason for giving up the practice of keeping them distinct. I may be asked where are they to be obtained. In former times Carey Tyso of Wallingford and Geo. Lightbody of Falkirk used to grow a grand lot of varieties they had raised from seed, and in their catalogues roots figured at half a guinea, and even a guinea each, but these good florists have passed away, and I really do not know of any English grower for sale. Collections may be obtained from some of the Dutch growers, but it will be necessary to weed them out very carefully when they bloom (many semi-double, &c., show the eye very soon); and by thus selecting the best, by degrees, a good collection may be obtained. There is also a class called French; they are showy in a border, but will not satisfy the ideas of those who have been accustomed to the refined and beautifully formed Dutch varieties.—D., *Deal*.

#### NATIONAL ROSE SOCIETY'S FIXTURES.

I WAS very much astonished to read in a letter signed "J. B." (page 109) that the reason, or the chief reason, for the retirement of Messrs. Hall and Whitwell from exhibiting was the early date of the Metropolitan Shows of the Society. I was perfectly sure, as they were intimate friends, that it was not so; but to make assurance doubly sure I wrote to both of them, and have received a reply to say that there is no foundation whatever for the statement. In both cases it was the excessive fatigue and anxiety that led to their retirement, and the date of the Metropolitan Shows had nothing to say to it.—D., *Deal*.

#### ROSES AT THE WOODBRIDGE SHOW.

ROSES are always a special feature at the Exhibition of the Woodbridge Horticultural Society, and the 25-guinea challenge cup with the National Rose Society's silver-gilt medal, offered for twenty-four distinct blooms, ought to bring forth a good competition at the Show on July 13th. Last year this coveted prize was won by Mr. Frank Cant.

#### THE ROSE DERBY.

IF I have made an incorrect statement as to the date in which my friend Mr. Grahame's name first appears as a member of the National Rose Society I hasten to express my regret for so doing and at once apologise. I have before me the N.R.S. reports for the years 1885 to 1892 (the previous years I have mislaid), and on looking through the list of members given in these last eight years' reports I observe that Mr. Grahame's name appears for the first time in these lists in the report for 1889. Hence my statement. I gather from Mr. Grahame's remarks that he has been a member of the N.R.S. since 1878, and therefore conclude that the list of members published in the N.R.S. annual reports is in some years incomplete. I am, moreover, exceedingly sorry to have vexed him in any way by my criticism, but to correctly estimate the strength of northern Rose culture, and the date of the northern season, one should be in a position to do so from lengthened experience and personal observation.—JOSEPH H. PEMBERTON.

#### TEAS IN MIXED CLASSES.

"J. B." (with whom I am very glad to be more in accord than used to be the case) finds a grievance (page 109) in the fact that boxes containing only Teas were allowed to win in classes for "Roses" at the Metropolitan Show. But surely this does not prove that "especial favour" was shown to them. If the Judges considered them better as "Roses" than the other boxes, why should they not win? It seems to me that, to be equitable in his contention, "J. B." should also consider that a winning box of H.P.'s only, in the mixed classes, would be a mark of "especial favour" to H.P.'s.

It is not many years since the amateur champion trophy was won by a forty-eight which had not a single Tea in it; yet none of the "Tea men" dreamed of complaining. Would "J. B." like a rule that there must be a certain number of Teas in exhibits in the mixed classes? for that seems the fairest form of his suggestion, unless he would have a separate department for H.P.'s only.

Many thanks to "Y. B. A. Z." (page 109) for his notes on moss; but there should not be much difficulty in the moist Fern-growing counties of the West of which he speaks.

In my last letter (page 108) an accidental omission (in my MS., no doubt) makes it seem as if I had wilfully misunderstood "D., *Deal*'s," assertion that it is "a very idle matter to compare the arrangements of a great show at the Crystal Palace to any provincial one, however good."

He adds, "In the latter you are confined to one tent, and you can get to any part of it in a couple of minutes, not so at the C.P., as many know to their cost." Quite so, but we have twice at least had to show in a tent at the Crystal Palace, and I appeal to exhibitors on those occasions as to whether there was any improvement in the arrangements and general convenience.—W. R. RAILLEM.

#### ROSE SHOWS.

It is quite refreshing to read the little duel in words which has been going on in "our *Journal*" concerning Rose Shows, the date thereof, and proxy voting. Now, instead of all this bantering is it not time we turned our attention to something a little more artistic, and at the same time natural in our exhibitions? We are too formal. What is more hideous than the long line of boxes, some of them evidently in need of a good scrubbing, untidy dingy-looking moss, the names of the Roses on wide pieces of cardboard very much *en evidence*? Then again, the stiff arrangement; scarcely a bud to be seen, nothing but the huge show blooms. Why cannot we break through this formality? Why not offer prizes, good substantial American prizes, for the best naturally arranged group to comprise some of all the different sections of the "national flower." Let us have masses of bloom. What can be more lovely than large bunches on long stems of such varieties as L'Idéal, Gloire de Margottin, and Laurette de Messing placed in a large vessel of water so that they are worth looking at by the time the public are admitted, instead of drooping as is now too often the case. Plenty of space should be allowed for these groups. Overcrowding is the crime of the present day, both socially and horticulturally.

I maintain that the National Rose Society should be the first mover in this innovation. Let us have a show worthy of our country. Why need we be dependent on the Crystal Palace Company? Could it not be arranged with the Royal Botanic Society to hold the show in their splendid gardens? There is no better place near London for holding an exhibition. I have often been surprised that the R.H.S. has never endeavoured to amalgamate with the R.B.S. and thus have a place of meeting worthy the name instead of the miserable Drill Hall.

Then, again, there is the question of the medal Roses. Could not a prominent place be set apart for these, so that when selected they could be brought together and thus their beauty seen to the best advantage?—W. E.

#### ATTAR OF ROSES.

It is well known that the great centre of the production of Attar, or Otto, of Roses occupies the northern portion of the old Turkish province of Eastern Roumelia. The cultivation of Roses for this purpose is, however, limited to the southern slopes of the Great Balkans, as the flowers are nowhere produced successfully on the north. The distillation of the petals is carried on in a very primitive manner with a copper still of the simplest construction. The first runnings are returned to the still, and the second are received in glass flasks, where they are kept for a day or two at a cool temperature to allow the oil to rise to the surface. From the latter it is skimmed by a small tin pipette or funnel, with a long slender handle attached to the top, and a very small aperture at the lower pointed end. This funnel is not more than three-quarters of an inch diameter at the widest part, so that it is easily inserted into the flask, and plunged below between the oily layer and the water. It is then at once brought up, and it brings with it a portion of the oily stratum with a small quantity of water. The water escapes through the aperture at the bottom, while the oil or otto is emptied into the collecting flasks. For exportation the commercial attar is transferred to flat circular zinc receptacles known as "coppers," which are carefully sewn up in white felt and sealed with the exporter's stamp, the brand being also stencilled on the felt outside. Two of these "coppers," one covered with the felt, and the other without, are contained in the Museums of Economic Botany at Kew, and to these Messrs. Piesse & Lubin have now courteously added a specimen of the pipette or funnel for the purpose of making the collection more complete. As regards the identification of the plants cultivated for attar of Roses, it may be useful to mention that in 1874 the late Mr. Daniel Hanbury, F.R.S., presented to the Kew Herbarium specimens of "Roses cultivated on the slopes of the Balkans for the production of attar of Roses, received from Mr. Vice-Consul Dupuis of Adrianople. These contained specimens of two species, a red Rose (*R. damascena*, *Millar*), and a white Rose (*R. alba*, *L.*). Neither of these is known in a wild state, and there can be little doubt that both are hybrids between *R. gallica* and *R. canina*. The subject is more fully discussed in "Pharmacographia" (1879), page 262.—(*Kew Bulletin*)

#### CANKER IN FRUIT TREES.

(Continued from page 116.)

MR. KRUSE (page 564 last vol.) mentions subsoil without defining it, but I assume that is the cause of the mischief, and where the iron exists in much greater percentage than is shown by the analysis. That being so, the soil, a deep friable loam, incumbent on an aluminous, calcareous, ferruginous, and silicious subsoil, more or less agglomerated, naturally or artificially under-drained. We may consider Mr. Kruse's propositions.

1, Iron in the soil or subsoil. An excess of iron is more likely to obtain in the subsoil and produce mischief in the trees after the roots reach it than a deficiency of available iron in the soil. Neither, however, are other than harmful. It is easy to supply iron, and in doing so still further charge the subsoil with oxide of iron, and though a tem-

porary advantage may be gained, the evil is only permanently aggravated. What must then be done? Supply iron in an available form, say sulphate of iron  $\frac{1}{2}$  to  $\frac{3}{4}$  cwt. per acre early in the spring whilst the ground is wet. That will supply the trees with iron and sulphur for some years, say three, because it is better in practice to apply a manure, if sulphate of iron may be called one, in effective, but not excessive, quantities at one time than spread the applications over a number of years in infinitesimal proportions. Oh! The iron will be washed into the subsoil. So it will, but the cultivator's business is to prevent such an occurrence. How? See to the analysis—iron low (3.38 per cent.), something else is low also, namely, nitrogen (0.17 per cent.) equal to ammonia (0.21 per cent.)—less in fact than a productive chalk soil. Therefore we must apply ammonia or the substance essential to its manufacture—that is “muck,” farmyard manure. Mr. Kruse is right. The land wants ammonia to ammoniate the otherwise unavailable iron in the soil and subsoil which the Apple and Pear tree roots have reached. Twenty-one tons per acre every third year of good farmyard or stable manure would not be too much, supplemented in the second year with a dressing of Thomas' phosphate (basic slag) 5 cwt., kainit  $2\frac{1}{2}$  cwt. per acre, applied in February, and  $1\frac{1}{2}$  cwt. nitrate of soda supplied at three times in equal proportion—namely,  $\frac{1}{2}$  cwt. when the blooms are expanding, the next  $\frac{1}{2}$  cwt. when the fruit is well set and swelling, the third  $\frac{1}{2}$  cwt. when it is half swelled. In the third year bone superphosphate 3 cwt., nitrate of potash 2 cwt., sulphate of lime 1 cwt., mixed, per acre, applied in spring will be beneficial. In the fourth year apply another 21 tons dressing of manure in autumn or early spring, and the  $\frac{3}{4}$  cwt. of sulphate of iron also in the fourth spring, always on the bare ground, leaving it for the rains to wash in.

2, “Would sulphate of ammonia be a suitable manure (of course, phosphorus and potash being added), bearing in mind it is a limestone soil?” How a limestone soil? Is it incumbent on limestone? or chalk, running into silicious matter and forming Kentish rag? That does not matter; the analysis does not show a limestone soil, yet for a loamy soil a liberal percentage of lime, which does not militate against the use of sulphate of ammonia, especially as the soil contains as much alumina as a free working clay soil; and  $3\frac{1}{2}$  cwt. of sulphate of ammonia per annum represents the equivalent of 21 tons of stable manure spread over three years. That quantity ( $3\frac{1}{2}$  cwt. per acre) would, no doubt, supply Mr. Kruse's cultures with the essential nitrogen, and penetrate the soil more rapidly and deeper than the ammonia of ordinary farmyard or stable manures; consequently the iron would sooner become ammoniated and available. Where, therefore, Mr. Kruse may not employ ordinary farmyard or stable manure, sulphate of ammonia should be applied instead, not every year, but on some rotary system, which is better than applying the same substance to the same soil and crop every year consecutively. Nevertheless the amount of potash and phosphoric acid are so good in the analysis that there would, perhaps, be no depreciation in the crops were the manures limited for some years to come to nitrogenous alone, say sulphate of ammonia one year and nitrate of soda the other, applying them as before advised.

Mr. Kruse used chloride of sodium (common salt), which I think is a mistake, as chlorides hinder the acid secretions of tree roots, often cause the foliage to become sickly, and on heavy soils are best avoided. For that reason kainit is objectionable. Salt and kainit are best applied to light or free soils; but not both, as kainit contains 40 per cent. of chloride of sodium (common salt), and enough sulphate and chloride of magnesium without special applications. On soils derived from chalk or limestone, kainit is best applied in the autumn, and it is only in those soils that are poor in potash that it can benefit. To apply potash where the soil contains abundance, as Mr. Kruse's, is to waste money, as it affords little or no benefit, nitrogenous manure being far more beneficial where there is no lack of potash and phosphoric acid. Far less potash, phosphoric acid, and nitrogen is required per acre when they are supplied in soluble form in the proper quantity, and at the right time, than when given in the form of stable or farmyard manure, one-third of the nitrogen of which, according to M. Ville, is lost to the soil on account of the decomposition the manure must undergo before any good accrues. Besides, fruit trees only need supplies of food six or seven months in the year, and though the manufacture of available plant-food is less in the winter than the summer, some is made, and a large per-centage is washed out by rain, so that substances lying in the ground must suffer considerable depreciation in manurial value to the crops. Therefore, by using chemical manures adjusted to the requirements of the crops, and supplying them so as to get their components in those crops instead of losing the major part, as in natural manures, we save immensely, and as the time of applying manures is an important one it may briefly be referred to.—G. ABBEY.

(To be continued.)

#### NOTES ON PEAS.

MR. H. S. EASTY (page 91) broaches a seasonable topic. With Peas, like Potatoes, I consider too many sorts a nuisance, except perhaps to the exhibitor or the lover of novelties. With the exception of the earliest kinds I am of opinion that Duke of Albany, The Duchess, Fortyfold, Veitch's Perfection, and Ne Plus Ultra will not only be hard to beat for all purposes, but are quite enough to supply any family. I am positive that they combine the two essentials, freedom bearing and quality. What more is needed I cannot say. With the exception of Veitch's Perfection, all the other sorts will succeed any-

where with reasonable treatment. The first named can be ready for gathering the first week in July, and sometimes the end of June, by sowing in pots, growing the plants carefully, afterwards planting them out in a properly prepared site.

At one time I thought the Duke of Albany Pea could not be beaten, but it can, and by the Duchess. The advantage of the latter is that it grows taller, consequently more pods are produced, these individually being longer, while the quality is equal. Fortyfold is an old variety, but for cropping and quality it is still unbeaten. It is not an exhibition Pea, perhaps, but that is not an important matter with everyone. Veitch's Perfection is too well known to require comment. In many districts this is the only variety grown for market—a sufficient test of its goodness. I am acquainted with a nobleman's gardener who grows no other sort than Ne Plus Ultra except first earlies. This is high praise for this Pea, which is usually looked upon as being so well suited for the latest crops.

Opinions vary on the quality and usefulness of the early sorts. I prefer Cannell's English Wonder to any other. William I. may produce a full crop of pods, but the peas are of inferior quality as compared with many others. Not only are the Peas that I have named excellent in cropping and flavour qualities, but with one exception—Veitch's Perfection—they are all of robust habit and not susceptible to mildew. If a regular supply of, say, two dishes per day can be gathered from these sorts from the time the second earlies come in at the end of June until the end of September, and often the end of October, what more in the way of variety is needed?

I may be told that as all but one of those named are tall growers, the difficulty of obtaining stakes is detrimental to their employment. However, not feeling that inconvenience, and knowing so well the advantage of tall growing sorts over those dwarfers, I intend to adhere to my favourites until I find better.—E. MOLYNEUX.

#### EXPERIENCE IN HEATING.

REGARDING “E. M.'s” criticism of my views upon the subject of heating (page 108), I should be very sanguine if I expected everyone would agree with them. It would be singular if they did. They are simply a record of some of my observations, and may possibly be of use to a few. I will first offer some explanations, also take exception to a few points in “E. M.'s” analysis.

Respecting the introduction of flow pipes into houses, I was of opinion, until taking charge here, that hot water would readily circulate to almost any reasonable height vertically. I have found out since it is one of those theories that do not always work out so satisfactorily in practice. Where fewer structures are heated from one boiler the case would probably be different, there not being such a complication of bends. This tends to promote friction, or where a large number of houses in one range are all heated at about the same level from the mains, presuming the boiler is fixed in a central position, as it should be, the connections at the bottom of these vertical pipes are often as hot as is possible to bear the hand upon. Up them the heat will not go. The pipes being full of water, and no accumulation of air, this occurs in several houses at different times. I wish I was in the position to satisfactorily explain the matter. I can only make a suggestion. With such a number of ramifications, the houses near the boiler containing pipes of easy gradients have, as it were, a circulation of their own. There the heat is obtained quickly, consequently there is a large quantity of hot water in close proximity to the boiler. It seems to me to prevent the colder water in the return main from the distant houses flowing past it. Someone will perhaps say, Check the heat on these houses. Conditions required do not always allow of that to any extent. Often the return main from these midway houses is fairly hot; 2 feet from it, in an upward direction, the same main is correspondingly cold. No amount of manipulation will alter this for a considerable time. I should add the boilers are fixed at one end of the arrangements, not in the centre.

“E. M.” takes exception to the arrangement of the pipes along the front wall. From my experience it is immaterial whether the Vines are planted 18 inches in front of them, or the pipes fixed 18 inches in front of the Vines if the heat is judiciously managed. As a matter of fact the Vines in the lean-to houses here are within 4 inches of the front pipes, the stems protected by boards. Of course I do not advocate that system; I only wish to point out that it does not affect the break of the Vines or the finish of the crop. Proof having been given of that, I do not regard this matter of a few inches of such importance as some cultivators do, neither do I see any improvement in connecting five flows into one return over that of connecting four flows into two returns. It must be a warm corner where these five flows converge, no fear about the wood ripening. One pipe can hardly be expected to receive the contents of five very rapidly.

Iron girders in place of piers, and stone colour paint in place of red, will have little effect on the produce. I use red lead, as being more durable against the action of the water. I quite agree with “E. M.” that iron borings make the soundest joints. With the exception he points out, perhaps all underground pipes would be best made so. Care must be exercised, however; if too much sal ammoniac is used among the borings, as employed by some, there is danger of bursting the sockets. Hot-water tanks for propagating purposes are good; but, as in many other things, expense often stands in the way of their provision.—J. J. CRAVEN, *Allerton Priory, Liverpool.*

**EVENTS OF THE WEEK.**—The ensuing week will not be a particularly busy one so far as horticultural events in the metropolis are concerned. On Monday, February 20th, the annual general meeting of the National Chrysanthemum Society will be held at Anderton's Hotel, Fleet Street, E.C., at 7 P.M. The customary auction sales will also take place at Messrs. Protheroe & Morris' Rooms.

— **THE WEATHER IN LONDON.**—The weather in the metropolis continues to be unsettled. Sunday proved cold with occasional showers, Monday being rather milder. On Tuesday it rained more or less the greater part of the day, and was squally. Wednesday opened fine with south-westerly winds, and at the time of going to press it appears to be more settled.

— **WEATHER IN THE NORTH.**—With the exception of Sunday, which was a fine, clear, cold, winter day, the past week has been a disagreeable one. Cold showers were frequent during the earlier part. The nights of the 9th and 10th were very boisterous and wet. During the night of the 12th 8° of frost were recorded, and on Monday morning the hoar frost lay like snow. Heavy snow fell all the afternoon and evening, but it changed to rain later.—B. D., *S. Perthshire*.

— **GARDENERS' ORPHAN FUND.**—We have pleasure in announcing that Baron Ferdinand de Rothschild will preside at the annual dinner of this charity on Wednesday, March 22nd, at St. James' Hall, Regent Street, and we trust a large and influential company will assemble on the occasion.

— **THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—As an instance of what local societies are able to do in aiding the gardening charities, we are asked to mention that the Reigate and District Chrysanthemum Society has remitted to the Gardeners' Royal Benevolent Institution no less a sum than £136 10s. during the four years it has been established, and has thus been the means of nominating thirteen of its members as life members of the Institution. Mr. James Brown, the indefatigable Honorary Secretary of the Reigate Society, expresses a hope that kindred societies, if able, may be induced to do likewise, and thus not only add to the funds of an excellent charity, but also benefit their own members by conferring upon them, as funds permit, the privileges of life membership of the Institution.

— **GARDENING AND FORESTRY EXHIBITION.**—Just as we are going to press we receive a preliminary programme of the Earl's Court Exhibition during the present year. It is intended to have a continuous representative display of Gardening and Forestry, with special fortnightly shows. The outline schedule appears to be very comprehensive, but particular reference to it cannot be made this week. Mr. H. E. Milner is Chairman of the Exhibition Committee, and Mr. Harry Turner, Slough, Vice-Chairman of the horticultural section.

— **CERTIFICATED PLANTS, 1859-1893.**—A more useful volume than that just published by the Royal Horticultural Society has seldom been issued. This comprises upwards of 250 pages, and contains the names of plants, flowers, Ferns, Orchids, fruit, and vegetables certificated by the Society from 1859 to 1893. The contents are admirably arranged, the work having been accomplished by Mr. John Weathers, Assistant Secretary of the Society. The book will be most valuable for reference, and should have a place in every library of horticultural works.

— **THE WORLD'S FAIR AT CHICAGO.**—We are requested to announce that for the convenience of visitors to Chicago during the forthcoming Exposition, a mammoth hotel is being erected by the World's Fair Co-operative Bureau. The hotel is in blocks, somewhat after the plan of St. Thomas's Hospital, and will contain over 6000 rooms. These rooms will be let at a uniform rate of a dollar a day to those who pay a nominal registration fee beforehand, and thus secure the right of occupancy at any time during the Exposition. The sole representation of the World's Fair Co-operative Bureau in Great Britain has been placed in the hands of the City Press Agency, 1, King's Arms Yard, and 51, Coleman Street, London, E.C.

— **EARLY PRIMROSES.**—A correspondent writes:—"Some fine bunches of Primroses were plucked on Saturday, February 4th, at Penhale, near the Lizard, the weather being delightfully fine and warm."

— **FLOWER SHOWS AT READING.**—We are requested to state that the summer Show of the Reading Horticultural Society will be held on August 16th this year, and that the Exhibition of the Reading Chrysanthemum Society will take place on November 15th.

— **FROZEN FLOWERS** are likely to become as plentiful as frozen meat. At a recent meeting of the Scientific Society of Ipswich, it was stated that a large consignment of flowers packed in ice would shortly be received from New Zealand. It is probable that the frozen flowers will be exhibited at the Museum at Ipswich.

— **SHEFFIELD BOTANICAL GARDENS.**—According to the Committee's report recently submitted, the outlook for these Gardens is not very promising. It would seem that the shares are at almost nominal prices, and unless more adequately supported by the townspeople fears for the future of these grounds are likely to be entertained.

— **THE BIRMINGHAM GARDENERS' ASSOCIATION.**—Three years since it was determined by the Association that an annual social gathering of members, their wives, and friends should take place at one of the principal hotels, and the anniversary meeting was held on the evening of the 8th inst., when a large number spent a most pleasant evening, Mr. W. B. Latham presiding.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The monthly meeting of this Society was held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday evening last. The chair was taken at eight o'clock by Mr. W. P. Thomson. Seven new members were elected, and one was nominated. Two members only are on the sick fund. The annual meeting will take place at the above hotel on Monday evening, March 13th, at eight o'clock. Mr. Arthur Veitch has kindly consented to preside.

— **THE ROYAL HORTICULTURAL SOCIETY** will hold a grand flower Show in the Agricultural Hall, London, on August 29th to September 1st next, when it is intended to make special awards for heating apparatus and appliances that are practically tested in the building. These awards will prove of the greatest value in promoting trade, and the action of the R.H.S. in insisting that the awards shall alone be for demonstrated and proved merit should commend itself to general exhibition authorities.

— **FLOWER SHOWS AT THE CRYSTAL PALACE.**—The dates of the Shows to be held at the Crystal Palace during the current year are as follows:—The spring Exhibition of plants and flowers will be on Saturday, March 25th, and the Great Summer Exhibition on Wednesday and Thursday, May 10th and 11th. The National Rose Society's Exhibition is fixed for Saturday, July 1st, and the National Dahlia Society's Show will be held on Friday and Saturday, September 1st and 2nd. November 3rd and 4th are the dates of the grand Chrysanthemum Exhibition.

— **LYCHNIS CHALCEDONICA.**—Mr. S. Arnott (page 106) rightly says much in favour of the double form of this perennial. I should like to add a word in reference to the common form as a border plant. In cottage gardens it is much grown and appreciated, and goes under the name of "Scarlet Lightning." In strong soil it will reach 4 feet in height and give abundance of its showy flowers. Unlike many other hardy plants, it is easy to keep in its proper position in the border. By the aid of a fairly stout stake compact plants are assured, and with but little trouble in the matter of tying.—E. M.

— **COST OF MANURING FRUIT TREES.**—If you have not closed discussion on manures, will you allow me to say, speaking from considerable experience, that if a fruit garden is in a good condition an expenditure of from £1 to £1 10s. per acre every year in artificial manures will keep it so? I have always used Lawe's guano at about the rate of 2 cwt. per acre as a minimum, using rather more after a heavy crop. I have applied it at times varying from early February to late April, but prefer the former date. In conclusion, I would say young fruit trees planted in properly prepared ground need no manure for the first few years, and at all times it is possible to use too much.—Y. [Our correspondent is a highly successful cultivator—one who really makes fruit-growing pay in a district where the natural conditions are far from being of the most encouraging nature.]

— **BEAUTIFUL PRIMULAS.**—A box of Primulas arrive from Messrs. James Veitch & Sons only just in time for brief acknowledgement. The blooms are distinctly beautiful. Chelsea Scarlet, glowing in its richness; Chelsea Rose, large and charmingly tinted; Fern-leaved White and Chelsea White, large and pure; Chelsea Red, dense reddish purple; and the Double Rose, Crimson and White, are of first-class character. Chelsea Blue is also included in the high meritorious collection of massive flowers which represent superiority both in strain and cultivation.

— **GIFT OF RARE AND VALUABLE BOOKS.**—Mr. Thomas Hanbury, F.L.S., of La Mortola, Italy, has presented to Kew a selection of about thirty volumes, in memory of his brother, the late Daniel Hanbury, F.R.S. (part of whose library they formed), an accomplished botanist, who successfully devoted himself to the investigation of the sources of vegetable drugs. He published, in conjunction with Prof. Flückiger of Strassburg, "Pharmacographia," which will long remain the standard and classical authority on the history of drugs. The portion of his library now acquired by Kew is of especial interest as having been used by him in the preparation of his book. Most of the books treat of economic or medical botany, and several of them are of very early date. A fifteenth century translation of an Arabian author (Serapion) on medical plants, the *Kew Bulletin* says, is of special value.

— **BRITISH FUNGUS FLORA.**—Mr. G. Massee has published the first volume of a new synopsis of all the fungi hitherto detected in Great Britain. This volume, says the *Kew Bulletin*, contains the first part of the Basidiomycetes, including the genera Lycoperdon, Boletus and Polyporus, and the Agaricineæ. It is wholly in English, and, in addition to the description, critical notes by various authors are given under many of the species. Spore measurements are given of all the types or authentic species in the Kew Herbarium. It is twenty-one years since a complete British Mycological Flora was published—namely, Cooke's "Handbook," and during that period the number of known British fungi has been nearly doubled. That work contained 2810 species, and Mr. Massee estimates the present number at 4895, so that a new work is very much needed. In fact, students of mycology in this country have been at a standstill from the want of a complete synopsis.

— **THE WITCH HAZELS.**—During the dull days of winter, when most of our hardy shrubs are at rest, it is quite cheering to see a group of these charming plants covered with their beautiful bright yellow blossoms. Hamamelis virginica is the best known, though it is not grown so extensively as its good qualities warrant. In addition to being a valuable winter-flowering shrub, the foliage assumes some most pleasing tints during autumn. H. arborea and H. japonica are well worth growing in every shrubbery. H. arborea is perhaps the best of the three, as it produces the largest foliage and finest flowers, and occasionally attains a height of 15 feet; it is, however, rarely cultivated in private places. All are of easy cultivation. They rejoice in a good, light, moist loam, but may be grown and flowered well in a much inferior soil. Propagation is generally effected by means of layers, though the two latter species are sometimes grafted on stocks of the former.—**CORNUS.**

— **CLOSELY STOPPING VINE LATERALS.**—Does Mr. Iggulden think his a fair test of the supposed benefits attending the closely stopping of Vine laterals? and is he prepared to stop the whole of the laterals on his Vines another season? If not, why not? He appears to have only experimented on one or two laterals to a Vine. Would not the length of the other laterals assist greatly in supporting the Vines and fruit, and does the size of a bunch and its general finish depend only on the leaves of the fruit-bearing laterals? All these are questions which require consideration. His experiments so far I do not consider at all conclusive. Certainly, a few well developed leaves are better than a greater number of weak and attenuated ones; but the practice where the rods are disposed 3 feet apart and the fruit-bearing laterals stopped two leaves beyond the bunch, and others from non-fruiting laterals encouraged to fill up any vacant space with good but not crowded leaves, I find always result in good Grapes. If Mr. Iggulden's views were adopted rigidly the rods need only be 2 feet apart, and if the bunches produced are of good size both in bunch and berry, and also well finished, the weight of Grapes should be much greater than is the case in the majority of vineries at present.—**A. YOUNG.**

— **APPLE WYKEN PIPPIN.**—The village of Wyken, Warwickshire, is famed for the well-known Wyken Pippin, an Apple of most delicious flavour, and marked with the familiar black speck. Here it was first grown, the original tree having been brought from Holland by Admiral Craven, and planted at the manor house, which was formerly part of the ancient residence of the Craven family. The Apple trees may be seen growing in nearly all the local gardens and orchards; but most of them are exceedingly old, and no effort seems to be made to perpetuate the variety. Vegetarians may, therefore, turn their attention to the vicinity with profit.—(*Birmingham Weekly Mercury.*)

— **LEEDS PAXTON SOCIETY.**—The seventh annual dinner of the Leeds Paxton Society took place on Wednesday evening, February 8th, at the Nag's Head Hotel, Leeds, when nearly seventy sat down to a very liberal spread. The usual loyal toast, proposed by the President (Mr. Fuller), being duly honoured, the Secretary (Mr. G. Cooper) read the annual report. During the year twenty-three papers have been read, the average attendance being twenty-four. The Chrysanthemum Show connected with the Society held in November was a success both in quality and number of exhibits, also financially, there being upwards of £15 added to the balance. Various other toasts followed. Mr. Hallbrook proposed "The Essayists," responded to by Mr. Campbell, who had given several instructive essays on hardy fruit culture. Altogether the evening was very enjoyable and a credit to the Leeds Paxton Society, which seems to be awakening into renewed vigour.

— **THE BIRMINGHAM AND DISTRICT AMATEUR GARDENERS' ASSOCIATION.**—This new Association has, we are informed, made a good start, and promises to become as successful as its promoters desire. Its objects are indicated in one of the rules:—"The Association is formed for the promotion and advancement of the science and practice of horticulture among amateurs by the holding of periodical meetings for the purpose of giving lectures or reading essays, and exhibiting the products and requisites of the gardens of members, and for the discussion of subjects pertaining thereto; also for the awarding of points to members for their exhibits. To watch and promote the interests of amateur gardeners generally, and to secure their proper representation on all important societies; also to afford facilities for the interchange of plants, cuttings, and seeds, and to promote the extension of allotment holdings." Mr. Alderman William White is President for the year, and Mr. W. B. Griffin, Derwent House, Moseley Road, Honorary Secretary.

— **ARE WEED KILLERS DANGEROUS?**—My answer to "T. W.," page 72, *Journal of Horticulture*, January 26th, is—I think not. We have a large aviary, in which about a hundred, more or less, of gold and silver pheasants have the run. There are about 300 yards run of walks in the aviary. I dressed these last summer with a weed killer without an accident to any of the birds, so I think it may be assumed it is safe to use with ordinary care; but I wish it to be understood that the walks were protected with fish nets raised about a foot above them by means of stout wire benders stuck in the ground; the net was stretched well over and pegged down on the grass, and was kept on from two to three weeks, during which time we had some heavy rain, that washed and cleansed the surface of the walks. We were careful to clear away any worms coming to the surface of the walks before putting on the net. The birds were continually running over the net, but they took no harm whatever.—**W. SALCOMBE, The Vineyard Gardens, Ticehurst, Sussex.**

— **PEACH BUDS DROPPING.**—It does seem as if there were some sorts of Peaches, notwithstanding the necessary precautions, that will drop their first flower buds when forced early, and yet this trouble is never met with outdoors. When I looked in on Mr. J. Dean, the gardener at Titsey Place, the other day, I found that he was starting his earliest Peach house. The flowers were just bursting. I asked if he were troubled with bud dropping, but he replied, No. He said, "We do not force too strongly at the first, rather we give such a gentle warmth that the roots and buds move together. Too often the heat at first is fierce, hence the earliest buds fall because there has been no commensurate root-action, and if the smaller side buds are saved it is because by the time they open the roots are active, then we give plenty of water in the autumn. Some growers cease to water when the fruits ripen, and then keep the roots rather dry to help to get off the foliage, hence the borders are never thoroughly moist during the winter in the same way that borders outdoors are." These seem to be, in his estimation the chief causes of early bloom buds on Peaches dropping.—**A. D.**

— ROYAL HORTICULTURAL SOCIETY'S JOURNAL.—Parts 2 and 3 of vol. xv., just issued, of the Royal Horticultural Society contains, as usual, much useful information. Apart from a report of the conferences on Begonias, Apricots, and Plums held at Chiswick last summer, the papers and lectures given at the Drill Hall during the year are embodied in the volume. The subjects dealt with are enumerated in the Council's report read at the annual general meeting on Tuesday, and published elsewhere in this issue, so other than saying that the papers are thoroughly practical and interesting, further reference would be superfluous. The volume comprises nearly 500 pages, and is illustrated. The reports of the committee meetings and descriptions of the plants, flowers, fruit and vegetables certificated during the past year, together with a good index, add interest and utility to the work. Its price to non-Fellows of the Society is 7s. 6d., and it can be obtained from the Society's offices, 117, Victoria Street, S.W.

— GARDENERS' ASSOCIATIONS AND SITUATIONS.—A very curious case occurred the other day at Kingston in relation to the connection of gardeners' associations and the finding of situations for gardeners out of place. A sub-Committee had been appointed at a meeting of gardeners held to consider the formation of an Association for the district, and this Committee met for the purpose. They were nearly at the conclusion of their evening's labours, dealing with a suggestion taken from the rules of the Reading Gardeners' Association, "that members out of place should have permission to make their wants known at any ordinary meeting," when one of the Committee remarked, "Why, I know of a place open now," and a second said the same. At the same time two gardeners wanting situations were mentioned, and it was agreed to give these men the needful information at once. This fact serves to show how very useful gardeners' associations might be made in helping members or others when wanting situations.—D.

— CRAFTY EXHIBITORS.—In the *Journal of Horticulture*, page 92, a correspondent mentions a delicate question with respect to an exhibitor gaining a prize for Roses, the said exhibitor not having any Rose trees in his garden. I do not think a visit on the show day would be wise, for the inspectors or judges might find Rose bushes in the exhibitor's garden. Why not appoint two or three of the Committeemen to inspect would-be exhibitors' gardens from three to ten days before the show? It is useless to think of sending only one person, particularly in the locality of the Crays. I have had a little experience of that kind there. The Society that I was connected with had a similar case to that mentioned on page 92. An exhibitor gained a first prize for Apples, although he had not any Apples in his garden. A year or two ago at the same place a would-be exhibitor was short of good Carrots for his collection of vegetables, so he purchased some to make up the deficiency; he was told that everything he had in his garden was made a note of, so he did not put in an appearance at the show.—HESSEWOOD.

— CYCLAMENS, PRIMULAS, AND VIOLETS.—I herewith send you blooms and foliage of the above flowers for your inspection. The Cyclamens and Primulas are making a fine show at the present time. The former carry about four dozen expanded flowers on each plant in 6-inch pots, with a large number of buds to open yet. The plants were raised from seed sown about eighteen months ago. The Primulas are not so fine as they were a week or so ago, but plants in 5-inch pots are 15 inches through, with four to six large trusses of flowers thrown well above the foliage. The Primula blooms represent Sutton's Giant Crimson, Purity, and Reading Blue. The Cyclamens, too, are Messrs. Sutton's strain. The Violets are Marie Louise, grown in cold frames, and they have flowered well this winter. I shall be glad of your opinion of the flowers sent.—J. HAWKES, *Lillingstone House, Buckingham*. [The flowers arrived in good condition, and not only exhibited evidence of cultural skill, but general excellence of the strains, the Cyclamens and Primulas being very fine. The Violets were also large and delightfully fragrant.]

### BRUSSELS SPROUTS.

IN a recent number of the *Journal of Horticulture* (page 66), I read "Brassica's" article on Brussels Sprouts and their culture, a subject I am interested in, having for a number of years back given special attention to the cultivation of this most useful winter vegetable. In his closing paragraph your correspondent mentions two varieties that he has been successful with, and one of these he calls Craig's Favourite, of Scotch origin. I take it for granted that this variety is the one raised over twenty years ago at Craigo Gardens, near Montrose, Forfarshire, by

Mr. Alexander Muir, the then much-respected gardener, now retired, and his place filled by one of his sons. I procured seed of this Sprout from the raiser twenty years ago, and grew the variety most successfully at Keithock, in the same county. I have also grown it here along with London Market, Aigburth, and others, all excellent forms; but to a certain extent the plants lacked the uniformity of the Craigo variety as to height and general productiveness, but the characteristics of the latter may have resulted from the seed being saved with special care. The plan adopted every season was to look the plants over, and select the best as to height and uniformity of sprouts. These were planted by themselves in the spring to produce seed, and this done year after year perpetuates a high-class variety. The same course adopted with any other vegetable will give truer seed than it is possible to obtain when many varieties are seeded together. The Aigburth and London Market I have crossed, but the result gave plants taller than others, and looser in the sprouts; but by perseverance this difficulty might in time be overcome.

I cannot understand why it is advised to sow Brussels Sprouts in a frame. Plants raised under glass have never the same hardy constitution that those have raised in the open ground. For many years I have raised my plants by sowing the seed in February in a warm border, the ground being well prepared, levelled, and raked, the seed sown very thinly, broadcast, and raked in. A good dressing of burnt ashes or potting-shed refuse is given, and then some fine leaf mould spread on the surface, which lies open, and the frost does not take the same hold of it, should it come, as in the case of closer soil. The seed being sown thinly the plants are sturdy and lift with fine masses of small roots; very different from long tap roots, the result of thick sowing.

To have really good sprouts the ground should be deeply cultivated and be in good heart, and the plants put in 2½ feet asunder towards the end of May or the first week in June and well watched. If kept clean the crops will repay the care bestowed.—A. KEMP, *Coolhurst, Horsham, Sussex*.

### NEW VIOLAS.

THE autumn of 1892 and spring of 1893 brings a goodly addition of new varieties, many of which I have seen, and am able to send you a few notes respecting them. First, I notice with pleasure that the florists of Scotland are now devoting more attention to the Viola than previously. There is a rapidly increasing demand for the lovely varieties of this popular plant, and new varieties of sterling merit are sought after. Messrs. Dobbie & Co. of Rothesay have been foremost in late years in growing a collection, and in producing fine varieties. They are now sending out twelve new sorts, and of these I have seen Laverock, an improved Skylark, a charming variety; Rob Roy, an improved Vernon Lee, very pretty; and Sylvia, a fine white, raised by Dr. Stuart of Chirnside.

Mr. Andrew Irvine, Tighnabruach, is introducing twenty-six new varieties, and he has secured the stock of Golden Flake, a lovely yellow; and Morning Dawn. These two fine varieties were raised by Mr. J. D. Stuart of Belfast, who is devoting great attention to Violas and Pansies. Another Belfast amateur, Mr. Samuel McKee, is also introducing some very fine seedling Violas through Mr. Irvine, who is sending out Comet; Countess, extra fine; Duchess, a beautiful variety; Magnet, a grand acquisition, so rich in colour and good in form; and Mars and Pearl. All these I have seen, and can recommend them. Mr. Irvine also sends out two of Mr. Frater's raising—Mrs. Hay and Peggy Smith.

Mr. S. Pye, of Cathwall, is sending out eleven new varieties, but as I have not seen any of them I am unable to speak about their merits. In addition he is introducing twelve new varieties of the Sylvia type, raised by Dr. Stuart of Chirnside, who is also the originator of the Violetta section. I have not seen Sylvia and its companion varieties in a growing state, only as blooms sent to me by Dr. Stuart, and these bore a resemblance to Countess of Hopetoun in form and colour. I was, moreover, led to suppose they partook of the excellent compact habit of the Countess of Hopetoun. Of these, Blue Gown, Bridal Wreath, Picotee, Sweet Lavender, and Sylvia, which I have seen, I can mention as acquisitions. Dr. Stuart is also sending out, through other florists, some varieties of the Violetta strain, very dwarf in habit, and with small well formed deliciously fragrant flowers, many of which I have seen, and amongst them Marginata and Summer Cloud are particularly pretty. Mr. George Steel, of Heatherslaw, is also devoting attention to seedling Violas, especially of the Violetta section, and his new varieties, Mrs. Joseph Oliver, Maggie Steel, Mrs. Stephens, Mrs. George Findlay, and Jeannie Turnbull, are all very pretty and fragrant. His lovely pure self-yellow Viola Beauty of Heatherslaw is also a welcome acquisition.

Some very fine seedling varieties of Violas raised by Mr. J. D. Stuart and Mr. McKee and others, I have seen, but they will not be introduced until next autumn, and these are in the hands of Mr. Irvine, who is also the possessor of the entire stock of Duke of Clarence, a very fine dark self. This variety was awarded a certificate at the Midland Counties Pansy Society.

Some beautiful acquisitions have very recently been made in Annie King, Bridesmaid, Colleen Bawn, Golden Gem, H. W. Stuart, Mary Gray, Master of Arts, Mrs. Frater, Gaiety, Princess Beatrice, Dorothy Tennant, Duchess of Fife, Beauty, H. M. Stanley, Lady Amory, Quaker Maid, Mrs. Charles Turner, Queen of Scots, Star, Sunlight, Sunrise, Wonder, and William Neil.—WILLIAM DEAN.

JOHN H. TAYLOR.

THIS variety is described by Mr. John Thorpe in the *Chrysanthemum* number of the "American Florist," November, 1892, as an early variety, and specially marked as such, not late. Amongst the best late varieties mentioned in "American Gardening" this variety is omitted by Mr. John H. Taylor. I attribute its lateness of flowering to late importation.—IMPORTER.

#### FAVERSHAM AND DISTRICT CHRYSANTHEMUM ASSOCIATION.

KNOWING the wide circulation your paper possesses I beg to inform you that this Association at a committee meeting held on the 10th inst. took steps to modify the conditions of their "Kent County Competition," referred to on page 116. They do not, however, see their way to do without the Reflexed varieties entirely, so have modified it thus—twelve blooms each Japanese and Incurved, distinct, and twelve Reflexed of not less than nine varieties.—C. E. CLINCH.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee was held on Monday last at Anderton's Hotel, Fleet Street. Mr. R. Ballantine occupied the chair, being supported by an excellent attendance of members and officials.

The minutes of the former meeting being disposed of, Mr. R. Dean (the Secretary) announced that Sir Edwin Saunders could not conveniently preside at the annual general meeting, and it was thereupon moved by the Chairman that one of the Vice-Presidents be asked to fulfil that duty. Mr. H. R. Williams of Hornsey will probably be the one to undertake it.

The sum of 2 guineas was voted to the Beanfeast Fund of the employés of the Royal Aquarium in accordance with the usual custom, and a letter from the Secretary of the Aquarium Company was read confirming the fixtures for the current year's exhibitions.

The Secretary presented a rough sketch of the annual report, which was approved, and will be laid before the members at the annual meeting next Monday. From the Secretary's statement it would appear that a balance will remain in hand far exceeding that of previous years.

The following Societies were admitted in affiliation:—Dalkey, Killiney, and Glenageary Chrysanthemum Society, the Rugby Society, and the East London Amateur Chrysanthemum Society, and fifteen new members were elected.

Mr. Earland, whose frozen blooms were awarded a medal last autumn, in acknowledging its receipt, referred to his work in that colony, and his expectations of New Zealand saved seed producing a very high percentage of good double flowers. He also promised to send over a further instalment at no distant date. It was mentioned that the cash subscribed to the special prize fund for 1893 now amounted to upwards of £128, in addition to which were several important special prizes of medals offered by Mr. Jukes, and a cup by Major Collis Browne. The affiliation scheme appears to be bearing good fruit, for at the present time there are exactly 100 Chrysanthemum and Horticultural Societies at home and abroad on the list.

Mr. Jukes, in calling attention to the annual meeting, reminded the members that there would probably be a large attendance and a good deal of business to be done. He hoped the Committee, who were really the working members of the Society, would all be present, and that country members would likewise muster in good numbers.

#### INCREASED SIZE OF STANDS.

"SADOC" (page 116) fears I do not realise the full benefits that would accrue from the use of a larger board. He then goes on to give a reason that is almost an echo of a case in point I made (page 76), and that "S." so ably dealt with (page 96) namely—that if a larger board was made "compulsory" the judges would be able to arrive at an accurate estimate of the merits of each particular stand with ease, and that without doing the amount of damage that is now so often a prominent feature of our shows. It is in the word "compulsory" that the gist of it all lies; without it, there is, and ever will be, as "D." puts it, "chaos."

What sane man, who has the welfare and improvement of the Chrysanthemum at heart, would dream of proposing an optional decrease in the size of stands for incurved blooms on the score of the present size board being too large for some of the growers of smaller blooms? Yet that is what the question of an "optional" increase in the size of stands for Japanese resolves itself into. Moreover, the problem will become more and more difficult of solution each year, for England has far from reached the zenith of her fame in giant Chrysanthemum raising; in fact, she has only just awoke to the importance of it, and we may rest assured it will not be "as you were" when she has had her fling.

My suggestion is, that where societies find their tabling space limited they should institute smaller classes, and ask for all distinct; for instance, "thirty-six Japanese distinct," would be equally or more

representative than forty-eight with duplicates allowed. Or in the case of smaller classes, "eighteen distinct" against twenty-four with duplicates. There would then be no extra tabling needed.—H. BROWN, *Beaurepaire*.

#### SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual dinner of the Sheffield Chrysanthemum Society took place at the Clarence Hotel, High Street, on February 8th. About sixty members, delegates, and friends were present. Mr. John Haigh occupied the chair, supported by Mr. B. G. Simpson as Vice-President, Mr. W. Housley (Secretary), Mr. H. Broomhead (Treasurer), Mr. J. G. Newsham, Mr. H. C. Robinson, Mr. R. H. Laughton, and others. Delegates were present from Wakefield, Leeds, Barnsley, and Rotherham, also from local horticultural societies. Letters of apology were received from C. E. Jeffcock, Esq., the President, Mark Firth, Esq., ex-President, the Mayor (Ald. Batty Langley), and G. Senior, Esq.

On the conclusion of an excellent repast, the toast of "The Queen and Royal Family" was proposed by the Chairman, who took the opportunity to refer to the honour conferred by the Queen in raising Sheffield to the status and dignity of a city. The toast was drunk with enthusiasm. The toast of the "Chrysanthemum Society" was proposed by Mr. J. Smith of Rotherham, who congratulated the members on the excellent show held in November, and stating that they in Rotherham were endeavouring to imitate them.

The Chairman acknowledged the toast, and spoke of the advance made in the cultivation of Chrysanthemums. Progress was still going on in the size and quality of blooms which could be produced. Some of the leading authorities had found it necessary to increase the size of the exhibition boards. The aim of the Society was to make their exhibition a credit to the city and a powerful means of spreading instruction and interest in the growth of Chrysanthemums. So long as the public upheld them, as they appeared to be doing, the members of the Society would be willing to cater for their benefit and delight.

"The Visitors and Kindred Societies" was proposed by Mr. Housley and responded to by Mr. Taylor (Rotherham Society), and Mr. R. H. Laughton (Walkley Society).

#### HAIRY CHRYSANTHEMUMS.

THE short note by "Sadoc" in the *Journal* for the 26th ult. (page 76) reminds me of the very decided tendency on the part of seedling growers to keep the ball rolling in whatever direction the Chrysanthemum may take. The latest departure in new Chrysanthemums is certainly the development of hairy-petalled varieties, and if the demand for them be at all worthy of attention we may be sure that large numbers of novelties in this new section will be forthcoming. The pliability of the Chrysanthemum is one of the chief reasons of its present popularity, for it seems we have only to ask for what we want, and in a season or two the want is supplied by ingenious florists either in Europe or America.

Five years ago Mrs. Alpheus Hardy was first announced in the American press, and a wonderful, though perhaps undeserved, stir it made. Louis Boehmer followed, then W. A. Manda and H. Ballantine. Last season *Enfant des Deux Mondes* was put into commerce by a Continental grower, and I may remind "Sadoc" that it is because this is a variety raised in France that it bears a foreign name. We can hardly expect French florists to give purely English names to their gains any more than the French can expect us to give French names to our new seedlings.

A Belgian correspondent, in a recent letter, informs me that he has raised from seed imported from the Imperial Gardens at Tokio a hairy variety of the Louis Boehmer type, but of a deep crimson colour, without, however, mentioning the name he intends to give to it. There is also a blush sport, which I have not yet seen, from Louis Boehmer called William Falconer, and at Camberwell there is another of the same parentage bearing the name Queen of the Hirsutes, and this is described as a ruby crimson coloured flower. I saw a bloom some time since; but it was one from a lateral growth, and was lighter than I should describe as ruby crimson. Crimson-amaranth seemed to me to be more appropriate; but verbal descriptions of colours in flowers are always open to question.

In an American catalogue recently to hand I observe a new yellow hairy variety called Zambesi, which does not yet appear to have made its way to this side of the Atlantic. It is reported to be an American seedling not synonymous with W. A. Manda, partaking of W. H. Lincoln in colour, with foliage resembling Mrs. Alpheus Hardy.

A further addition is promised from M. de Reydellet this year. Mdme. Ferdinand Cayeux, a pomegranate red, also raised from Louis Boehmer, was described by M. Godefroy Lebeuf in a recent issue of *Le Jardin*. M. Simon Delaux, the indefatigable raiser in the south of France, announces the distribution of several others this spring, so that the lovers of this new class of Chrysanthemum will soon be in a position to set up a good representative board of hairy varieties. Synonyms already look like being multiplied in this new class, for two of them have by some means acquired a second name.

Although the original variety came from Japan the hairy section appears to be limited in that country. A Japanese catalogue received last spring contains the names of only six varieties in cultivation there, and most of those can be approximately identified with the kinds now commonly cultivated in England.

It does not appear that the tendency to hairiness is inherent, for a correspondent in the States tells me that out of thirty seedlings raised from Mrs. Alpheus Hardy a few seasons since not one showed the least sign of that peculiarity.—C. H. P.

## CHRYSANTHEMUM NEW YEAR'S GIFT.

As a late flowering Chrysanthemum New Year's Gift is a decided acquisition, and will no doubt become a popular variety. Blooms of it

fine bloom from Mr. Owen during the first part of the current month, and from this specimen the engraving (fig. 25) has been prepared. The flower, as will be seen by referring to the illustration, is large, rather

FIG. 25.—JAPANESE CHRYSANTHEMUM, NEW YEAR'S GIFT.

were shown by Mr. R. Owen, Castle Hill Nursery, Maidenhead, at the Drill Hall on January 17th, and the Floral Committee of the Royal Horticultural Society adjudged an award of merit. As further corroborating its value as a late-flowering variety we received a wonderfully

flat, with broad florets, which are white. The variety is an English raised seedling of the Japanese section, and is said to be an excellent grower. For decorative purposes at this late period the blooms are most valuable.

## ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 14TH.

## THE COMMITTEES.

DULL, wet weather unfortunately prevailed on the occasion of the annual meeting, and this was to be regretted on account of the Exhibition alone, which was a bright, well varied, and beautiful one.

**FRUIT COMMITTEE.**—Present: Philip Crowley, Esq., in the chair, with Messrs. John Lee, T. F. Rivers, J. McIndoe, A. H. Pearson, A. Moss, Arthur Veitch, J. Cheal, W. Warren, T. J. Saltmarsh, A. Dean, A. J. Laing, G. Reynolds, W. Bates, G. Wythes, F. Q. Lane, H. Balderson, J. Smith, G. Norman, and J. Wright.

Specimens of Chou de Bedford from Mr. T. Laxton were placed on the table, this variety of the Portugal Cabbage being a cross between Couve Tronchuda and Chou de Burghley. They had a more general resemblance to the former than the latter. It was suggested that the variety be grown at Chiswick for testing in a cooked state.

A dish of Witloof was sent from Chiswick, crisp heads, esteemed for salading as well as in a cooked state.

Mr. G. Miller, The Gardens, Ruxley Lodge, Esher, sent a dish of Mushrooms (vote of thanks). Mr. S. Hardy, Ash House, Parsons Green, Fulham, sent large baskets of splendid Mushrooms as packed for market; very fine samples (cultural commendation).

A box of Peaches, imported from the Cape, was exhibited by P. A. Molteno, Esq. The fruits were small, but attractive in appearance, yet distinctly inferior in quality. They bore no comparison with our home-grown fruits, but these cannot be had in February (vote of thanks).

Mr. W. Roupell sent six varieties of Apples grown in his suburban garden at Streatham. They were all good, Newton Wonder being especially firm and fine (cultural commendation). Mr. W. H. Bannister, The Gardens, Cote House, Westbury-on-Trym, sent fruits of Standard Bearer Apple, a symmetrical oval-shaped fruit, tender in flesh and of good quality. An award of merit was granted by ten votes against six. Mr. R. Maher, Yattendon Gardens, sent bottles of jelly from Dumelow's Seedling and an unnamed local variety of Apple, but both samples were overpoured with sugar, which obscured the flavour of the fruit. Handsome fruits of Nancy Jackson Apple were placed on the table by Mr. Rivers; large, symmetrical, striped, and tender. Mr. McIndoe referred to the variety as the "coming Apple in the north." Rivers' Codlin Apple, certificated in October, was exhibited to show its keeping properties. The Reinette Dorée Apple was also placed on the table, a smallish, attractive, and tender fruit. Very fine specimens of Passe Crasanne Pear were cut and found excellent (vote of thanks). Messrs. Cheal and Son had a very extensive and imposing display of Apples on the side table, comprising 106 dishes of the leading varieties, well kept and well coloured. Amongst them was a dish of the new dessert Apple Armorer. It was raised by Mr. C. Ross, received an award of merit in 1890, and a first-class certificate in 1892. The fruit is small, russety, tender, also sprightly and agreeably flavoured; decidedly a good late dessert Apple that will probably make its way in the world. A silver-gilt Knightian medal was recommended for the collection. A similar honour was conferred for sixty dishes of Apples arranged by Mr. G. W. Cummins from the gardens of A. H. Smee, Esq., Hackbridge; remarkably clear, good, and well kept fruit. As the produce of a private garden the Committee thought the collection quite as meritorious as the larger one above referred to and hence the recommendation.

Wholly different from the above was the collection of fruit from Mr. Rivers. It included a dozen varieties of Oranges, fine, clear, ripe fruit, the St. Michael's being represented by seven large fruits in a cluster. Wadhurst Pippin Apple was splendidly shown, huge symmetrical striped fruit, grown in pots plunged in the open ground. Cox's Orange Pippin was exceptionally fine, and King of Tomkins County very good. A new Apple, Jacquin, was highly distinct by its waxy yellow appearance and remarkable firmness. This Apple should be cut and its quality tested at a subsequent meeting. In this collection large fruits of "Jupp's Surprise" were noticeable, that being the name under which the Apple was received from New Zealand, but Mr. Rivers correctly named it Bismarck, a fact worthy of record in view of possible future contingencies, for growers who have Bismarck may be satisfied without adding Jupp's Surprise, if it should find its way into commerce under this name. A silver-gilt Knightian medal was recommended for the collection.

**FLORAL COMMITTEE.**—Present: W. Marshall, Esq. (in the chair); Rev. H. H. D'Ombain, Messrs. H. Herbst, Robt. Owen, Owen Thomas, George Stevens, Chas. F. Druery, Walter Furze, John Jennings, Frank Ross, Chas. Jefferies, William Bain, C. J. Salter, T. Baines, Peter Barr, Chas. E. Shea, Chas. Noble, J. D. Pawle, George Paul, W. H. Williams, H. B. May, H. Turner, Geo. Nicholson, John Fraser, Ed. Mawley, and George Gordon.

Messrs. E. D. Shuttleworth & Co., Albert Nurseries, Peckham Rye, S.E., staged a very fine group of foliage and flowering plants, including Crotons, Dracænas, Azaleas, and Palms, and a number of Narcissi, which, for the time of year, were magnificent. Particularly prominent were bunches of Emperor, Henry Irving, Ard Righ, Countess of Annesley, Rugilobus, and obvallaris. A bronze Flora medal was recommended for this exhibit.

From the Hon. P. C. Glyn, Rook's Nest, Godstone (gardener, Mr. Friend), came some charming blooms of Camellias and a large Acacia dealbata, profusely flowered and deliciously scented (bronze Flora medal). Messrs. William Outbush & Son, Highgate, showed a group of Erica Wilmoreana, the plants being finely grown and excellently flowered (vote of thanks). From the same firm also came a collection

of Dracænas, conspicuous amongst which were D. Mrs. Fieake, D. Bella, D. angustifolia, D. superba, D. elegantissima, and D. vivicans (vote of thanks). A group of Chrysanthemum Golden Gem was shown by Mr. Mortimer, Swiss Nursery, Rowledge, Farnham, the flowers of which are of a lovely shade of yellow (vote of thanks). Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, showed a basket of Miss Joliffe Carnation (vote of thanks). Some very fine Amaryllises were sent by Mr. Perkins, gardener to the Viscountess Hambledon, Greenlands, Henley-on-Thames. The collection included amongst others the Hon. W. F. D. Smith, which was recommended an award of merit (see below), Viscountess Hambledon, and the Hon. Miss Smith.

A collection of Cyclamens was exhibited by Mr. Chas. Turner, Royal Nurseries, Slough. The plants were well grown and admirably flowered (bronze Banksian medal). Messrs. Hugh Low & Co., Bush Hill Park Nurseries, Enfield, staged a fine collection of New Holland plants, the most conspicuous amongst which were the sweetly scented Boronia megastigma, Diosma capitata, Acacia Drummondii, A. rotundifolia, A. armata, A. cordata, Erica melanthera, Chorozema Lowi, Correa cardinalis, Pimelea spectabilis, and Genista fragrans (silver-gilt Banksian medal).

Messrs. Paul & Son, The Old Nurseries, Cheshunt, sent some splendidly flowered plants of Lilacs, the white varieties being particularly fine. A group of Cœlogynes and some well-flowered plants of Lachenalias in variety were also sent by the same firm. The Lilacs shown by Messrs. Paul & Son were alba grandiflora, Marie Legrange (fine), Madame Abel Chatenez (white), and Mathieu Dombasle (purple). Messrs. J. Laing & Son, The Nurseries, Forest Hill, sent a Clivia (Imantophyllum) Exquisite, very fine truss. A charming plant of Pandanus Baptisti was shown by Messrs. J. Veitch & Sons, Royal Exotic Nurseries, Chelsea. Mr. R. Owen, Castle Hill Nursery, Maidenhead, sent very fine flowers of Chrysanthemum Beauty of Castle Hill (award of merit, see below), and also flowers of C. New Year's Gift, certainly one of the finest late whites, and illustrated on another page of this issue. Messrs. Garaway & Co., Durdham Down Nurseries, Clifton, Bristol, sent plants of Primula sinensis Garaway's White Perfection, the flowers and habit of which are excellent. Messrs. Robt. Veitch & Son, Exeter, sent two plants of the black Arum sanctum palestinum. They also sent a plant of Asparagus retrofractus arboreus—a fine variety.

**ORCHID COMMITTEE.**—Present: Dr. Masters (in the chair), Messrs. James O'Brien, C. Pilcher, T. W. Bond, E. Hill, Hugh Low, H. M. Pollett, W. H. White, Thos. Statter, E. Handley, T. B. Haywood, S. Cortauld, F. Sander, Jas. Douglas, Ed. Moon, and S. le Doux.

The display of Orchids was extensive and of much interest, the Committee having quite a busy time. Messrs. B. S. Williams & Son exhibited Cypripediums largely and well, the intermingling of a few other Orchids contributing diversity. Amongst the Cypripediums were Amesianum, Sallieri aureum, Measuresianum, Morganiæ, Fitchianum, nitens, gcmiferum, vernixum, and Pitcherianum Williamsi, all very healthy and well grown plants. Cattleya Trianae alba, Oncidium splendidum, and Lycaste costata being amongst the other Orchids shown (silver Flora medal). Messrs. Pitcher & Manda contributed a diversified and charmingly arranged group, one of the most pleasing which they have set up. Cypripedium Rowallianum, C. Boxalli atratum, C. Barteli, and C. magniflorum were very noteworthy, as were Cattleya Percivaliana and C. Trianae delicata (silver Banksian medal). Messrs. Hugh Low and Co. contributed a beautiful collection of Phalænopsis, which they grow splendidly. P. Stuartiana, P. leucorrhoda, P. amabilis, P. Stuartiana aurea, and P. Schilleriana vestilis were represented. The latter was awarded a first-class certificate, and is described below (silver Flora medal). Messrs. Paul & Son, The Old Nurseries, Cheshunt, had a beautiful display of Cœlogynes and Lilacs (silver Flora medal). The former comprised such varieties of cristata as maxima Lemoniana (Day's and Bockett's varieties) and alba. The plants were dwarf, compact, healthy, and full of bloom. Lord Foley, Ruxley Lodge, Esher (gardener, Mr. Miller), had a beautiful mixed group, comprising some finely grown Cœlogynes and Cypripediums, Phaius grandiflorus, and a number of stove and greenhouse plants (silver-gilt Flora medal).

Messrs. F. Sander & Co. had as usual an excellent group including many plants of special interest as well as a number of standard kinds. Arpophyllum spicatum, Lycaste Skinneri leucoglossa, Dendrobium × Sanderæ, D. Leechianum, D. nobile Amesiae, a superb variety of Lælia anceps named Schroderiana, Phalænopsis Sanderiana, P. Stuartiana, Platyclives glumacea, and Cypripedium Exul were finely shown, together with the novelties referred to under certificates and awards (silver Floral medal). C. J. Lucas, Esq., Warnham Court (gardener, Mr. Duncan), had Dendrobium Wardianum album, Angræcum lylaloides, and Cattleya Warocqueana alba, Linden's variety. Sir Trevor Lawrence, Bart., sent Masdevallia Schroderiana, and Cypripedium concolor (award of merit, see below). From the Royal Botanic Gardens, Glasnevin, came Diurus maculata, Smith, Eria barbata, Rehb. f., and Epidendrum xanthenum, Lindl., the two first-named receiving botanical certificates. Messrs. James Veitch & Sons contributed Epidendrum × Endresio Wallisi, Cypripedium × Winnianum, and Phaius × amabilis. The two latter are referred to under certificates and awards. C. Winn, Esq., Birmingham, exhibited Cypripedium The Duke, a cross between C. barbatum grandiflorum (pollen parent) and C. Stonei. It is a striking and distinct flower. S. le Doux, Esq., sent a small but interesting collection, several of the members of which received awards of merit, and are described elsewhere (silver Banksian medal). Mr. J. Crispin, Fishponds, Bristol, received a bronze Banksian medal for an attractive collection of Cypripediums.

## CERTIFICATES AND AWARDS.

*Phalaenopsis Schilleriana vestilis*, Rehb. f. (H. Low & Co.).—A lovely variety of Schilleriana, pure white, save for the yellow lip and for the orange-yellow spots around it. It is said to be the only plant in Europe (first-class certificate).

*Cattleya Trianae*, Hillingdon variety (W. Whiteley).—A very large and fine variety of the popular type, with satiny blush sepals and petals, and rich magenta lip; throat orange (award of merit).

*Dendrobium nobile Amesiae* (F. Sander & Co.).—A beautiful form, with white sepals and petals, and a rich maroon throat; very distinct and attractive (award of merit).

*Laelia hybrida Maynardi* (F. Sander & Co.).—A distinct bigeneric hybrid, obtained by crossing *Laelia pumila* Dayana (seed parent) with *Cattleya dolosa*. The long protuberant lip is rich carmine magenta, with purple flakes; sepals and petals rosy mauve (award of merit).

*Dendrobium Owenianum* (F. Sander & Co.).—A very fine hybrid, a cross between *D. Linawianum* majus (pollen parent) and a grand variety of *D. Wardianum*. While there is a resemblance to *Wardianum* in the flower, there is also distinctness, and the growth is different. The colouring is that of *Wardianum*, but the sepals and petals are more wavy and drooping (first-class certificate).

*Cypripedium Conco-Lawre* (Sir Trevor Lawrence).—This is a hybrid between *C. concolor* and *C. Lawrenceanum*. It is very distinct, and peculiarly coloured. The dorsal sepal is beautifully grounded and, like the petals and lip, is greyish white veined with rose (award of merit).

*Cymbidium grandiflorum* (F. Ross & Co.).—A well flowered plant of this very distinct and beautiful *Cymbidium*. It bore six blooms. These are of great size. The sepals and petals are of a dull pea-green with brownish dots towards the base. The lip is white spotted with brown and margined with green (first-class certificate).

*Cypripedium* × *Winnianum* (J. Veitch & Sons).—A hybrid between *C. Druryi* (pollen parent) and *C. villosum*. It is a harmony in brown. The petals are deep brown on the upper part, lighter below, with a broad central stripe. They are blunt and incurving. The lip is light brown, and the dorsalsepal purplish brown edged with lemon and margined with white (award of merit).

*Phaius* × *amabilis* (J. Veitch & Sons).—A cross between *P. tuberosus* and *P. grandiflorus*. The lip is brownish-red shaded with purple, this extending into the throat. The sepals and petals are blush veined with light brown. It is a dwarf grower, and apparently a free bloomer (first-class certificate).

*Cattleya Trianae Florence* (S. Le Doux, Esq.).—A very striking and beautiful form. The lip is of great length, soft satiny pink in hue, and the broad fringed lip rich purplish magenta, the throat yellow (award of merit).

*Mesospinidium vulcanum grandiflorum* (S. Le Doux, Esq.).—A plant bearing three flowering sprays of this bright little Orchid was shown. The flowers are of a bright rosy carmine, the leaves short and lanceolate (award of merit).

*Odontoglossum cirrhosum* Le Doux variety (S. Le Doux, Esq.).—A charming variety, the slender sepals and petals are thickly and evenly dotted with brown. It is of graceful habit and full of bloom (award of merit).

*Amaryllis The Hon. F. W. D. Smith* (Viscountess Hambledon).—A rich deep crimson shaded with purple, the segments broad and recurving (award of merit).

*Chrysanthemum Beauty of Castle Hill* (R. Owen).—A very fine and promising late Japanese, large and deep with slender incurving florets. The colour is pale yellow, deepening to bronze in the centre (award of merit).

*Apple Standard Bearer* (W. H. Bannister).—A symmetrical oval shaped Apple, tender in flesh, and of good quality (award of merit).

## ANNUAL MEETING.

THE annual general meeting of the Fellows of the Society was held on Tuesday afternoon in the Council Chamber, 117, Victoria Street, S.W. Sir Trevor Lawrence, Bart., President, occupied the chair. There was a very large attendance, the room being crowded to such an extent that many were unable to find seats.

The Secretary having read the minutes convening the meeting, forty-seven candidates were then proposed, and these duly elected. The appointment of scrutineers for the ballot of the Council followed, these being Messrs. J. Laing and A. Sutton.

Sir John Llewelyn, Bart., proposed a vote of thanks to the retiring members of the Council, Baron Schröder, Rev. W. Wilks, and N. N. Sherwood, Esq. In doing so, he said it was felt that none of these gentlemen had lost interest in the Society; indeed, they had expressed their desire that it should be recorded that the reverse was the case. Business matters, however, necessitated the retirement of Baron Schröder from the Council; but he would, they all knew, still continue to be deeply interested in the Society. He had, therefore, very much pleasure in moving the proposition. Mr. Harry Turner seconded the movement, and a vote of thanks was unanimously accorded.

Sir Trevor Lawrence, Bart., in moving the adoption of the report and financial statement, which were taken as read, remarked that in his opinion the Fellows of the Society and all interested in its work might congratulate themselves upon what had been accomplished during the past year. They had made steady progress, and this fact was set out in the report. One of the most important features was the great exhibition held in the Temple Gardens. This he regarded as being one of the most satisfactory flower shows that had ever been held. They were fortunate in the weather, and correspondingly fortunate in the

number of visitors. Regarding the work of the Society at Chiswick one could see by the report what had been done in this respect. The trial of a great variety of vegetables and flowers had been admirably carried out, as also had the evaporation of fruit. With the latter, however, he could not exactly agree, inasmuch as he considered evaporated fruit decidedly inferior to that in its natural condition. Reports had been received from Fellows who resided in the country, expressing themselves as being perfectly satisfied with what they obtained in return for their subscriptions. In previous years that had always been a great difficulty, but he thought it had been overcome, and success now achieved. The progress of the Society, too, as he had previously mentioned, continues to be satisfactory, and it was gratifying to know that already eighty-seven new Fellows had been elected this year. The numerical strength showed an increase of 206 new Fellows during the year, and a net increase of £278 5s. He would like to mention in reference to this that the Treasurer had calculated that for the ensuing year the income would be at least £4864, and the expenditure about £4535. If carried out this would leave a net profit of between £200 and £300. (Applause.) It would be noted that £386 had been spent in repairing the great vinery, but he was glad to say that, with the exception of two old structures, all the houses and buildings in the gardens at Chiswick were now in thorough repair. With regard to the scheme for examinations to secure Garden scholarships, that had given general satisfaction, and there was a prospect of a promise of assistance being given by the Government in such matters. Already seventy-two candidates had presented themselves for examination, and it was probable that there would be 400 or 500 before the year was out. It had been decided that the young men who succeeded in securing scholarships should work in Chiswick Gardens for the first year, and the second year in some good private garden, with the hope that they would develop into gardeners of first-class capacity. The Council was deeply indebted to the gentlemen who had read papers and given lectures at the periodical meetings, and an equally interesting syllabus had been prepared for the current year. There was one other matter he should like to mention briefly, and that was the question of life members. The Secretary, Treasurer, and himself had circulated a letter among the life members, and requesting them to become annual subscribers. Some thought such a step ought not to have been taken, but there were exceptions to the rule, and £41 had been received as annual subscriptions from former life members. Relative to the action in retaining the services of the Secretary as a salaried official the Council had acted strictly in accordance with the Charter. He could say that the Council felt the retirement of the Rev. W. Wilks would be a great blow to the Society, and that every effort should be made to retain his services. This, as they would hear, had been done. (Cheers.)

Professor Michael Foster, after the unanimous adoption of the report, rose to propose a resolution to the effect that the Rev. W. Wilks be re-elected as a paid secretary. Mr. Wilks, he said, was a secretary of no ordinary kind, and whether the Society regarded him for his business qualities, or for the great courtesy with which he treated all Fellows, it would be a difficult matter to meet with such a man. (Hear, hear.) Mr. Wilks was not only fond of gardening, but he had the interest of the Society at heart. About the time the South Kensington reign came to an end, it so happened that he had thought of Mr. Wilks, and in reference to him said, "that is the future secretary of the Royal Horticultural Society." He brought forward his name, and he might say that the progress of the Society—and they had made progress, although they had not yet removed from the Drill Hall, which might even yet be accomplished—was due to the exertions of Mr. Wilks. (Hear, hear.) It was therefore with much pleasure that he made the following proposition:—"That this meeting endorses the action of the Council in retaining the Rev. W. Wilks as paid Secretary of the Society, and resolves to insert a paragraph in the Charter authorising the adoption of the resolution." Mr. J. Hudson seconded the motion, which was carried unanimously.

The Rev. W. Wilks in returning thanks for the unanimous adoption of the resolution, said he was sure they would excuse him referring very briefly to the matter, inasmuch as he had only a few hours previously left his bed after suffering from a severe attack of influenza. He was almost sorry that the proposition had not, to some extent, been opposed, because it seemed to him that there must be someone connected with the Society who could fill the office of Secretary equally as well, or even better, than himself. (No, no.) Progress had been made, and since the Society removed from South Kensington there were not more than 200 or 250 Fellows of those days left. It seemed as if the old generation had passed away, and with it the South Kensington "Pleasure-garden policy." The new generation, as it were, had returned to the policy that the Society originally advocated, that is, assisting to make gardening not only a pleasure but a science, a skill, and a craft. There was not a Fellow who could not say that the Society had progressed; but mistakes had been made. It was almost impossible to accomplish years of work and progress without committing errors, but he would make an appeal, through the representatives of the gardening papers, that when any Fellows did find a mistake had been committed that they would write in a genial way direct to the Secretary, and point out the shortcoming. (Hear, hear.) It was no use writing to the newspapers making complaints; they should send to the fountain head. It was no part of the duties of a Secretary of such a Society as theirs to read the newspapers, and it sometimes happened that complaints made through this medium were overlooked. If the course he advised was adopted, he was sure the Council would meet the views of those who complained and endeavour to rectify matters. He would ask all present,

and others interested in the Society, to exert themselves and obtain new Fellows. All who like fruit, plants, and flowers should become connected with this Society, which for nearly a century had done so much good.

Sir Trevor Lawrence remarked that they were also indebted to Mr. John Weathers, the Assistant Secretary, who was most indefatigable, and always ready to do the work of the Society. He could also say the same of the clerks. As regards Mr. Barron, they all knew the value of his services, and were well acquainted with the admirable manner in which he carried out his duties at Chiswick. It was also announced that complete arrangements had been made with the Directors of the Agricultural Hall, Islington, in reference to the Exhibition of horticultural appliances at the end of August. He thought that one of the greatest disadvantages in exhibitions of this kind—the testing of exhibits—had been overcome, and the Show was likely to be a success.

During the meeting the scrutineers' result of the ballot was announced, and it was to the effect that Sir John Llewelyn, Bart., the Hon. Walter Rothschild, and J. T. Bennett-Poe were elected members of the Council. The following officers, in addition to Rev. W. Wilks, Secretary, were also re-elected:—Sir Trevor Lawrence, Bart., President; Philip Crowley, Esq., Treasurer; and Messrs. H. Turner, H. Williams, and A. H. Pearson, Auditors.

Votes of thanks to the Chairman and Auditors concluded the proceedings.

#### REPORT OF THE COUNCIL FOR THE YEAR 1892-93.

THE year 1892 has again been one of steady work and progress for our Society.

Two Conferences have been held at Chiswick—viz., on Begonias and on Apricots and Plums. The attendance of Fellows and others at these Conferences, as also at the fortnightly lectures in the Drill Hall, has continued to be more encouraging than in previous years. Fellows would greatly assist the Council by making these meetings and lectures better known among the general public.

Twenty-two fruit and floral meetings have been held in the Drill Hall, besides those held at Chiswick, and lectures have been delivered at nineteen of them. The number of awards has been as follows:—On the recommendation of the Floral Committee, 62 first-class certificates against 33 in 1891, 156 awards of merit against 183, and 2 botanical certificates. On the recommendation of the Orchid Committee, 48 first-class certificates against 34 last year, 72 awards of merit against 38, 29 botanical certificates against 10. On the recommendation of the Fruit and Vegetable Committee, 27 first-class certificates against 6, and 18 awards of merit against 7 last year.

The Society's Great Show held (by the renewed kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as great a success as ever, alike in the number of visitors, the quantity and quality of the exhibits, and the propitiousness of the elements. The best thanks of the Society are due to all who so kindly brought their plants for exhibition or otherwise contributed to the success of this Show.

The Society's general work of scientific experiment and investigation, and of the practical trial of various plants, has been going on steadily at Chiswick, under the superintendence of Mr. Barron. Trial has been made of 45 varieties of Tomatoes, 12 of Turnips, 79 of Runner Beans, 66 of Beet, 79 of Vegetable Marrows, edible Gourds, and Pumpkins, and 80 of Savoy and Cabbages. Eighty-nine new varieties of Potatoes, and 104 new Peas have been tested. In the floral department 200 varieties of Carnations and Picotees, and 50 of Pinks, 200 Dahlias, 80 Violas, 44 of Sweet Peas, 26 bedding Begonias, 324 Phloxes, 500 Pæonies, and 330 Asters (Michaelmas Daisies) have been tried. The Phloxes, Pæonies, and Asters have each had the special attention of a Committee of experts both in regard to their proper nomenclature and their value as hardy border flowers. The reports of these Committees will, it is hoped, be ready for publication during the present year.

Experiments have also been made with a fruit evaporator, kindly presented to the Gardens by Messrs. Mayfarth, and most satisfactory and encouraging results have been obtained in the drying of both Apples and Plums.

The Journal of the Society has been continued so as to enable Fellows at a distance to enter more fully into and reap the benefits of the study and work of those more actively engaged at headquarters. The first part of vol. xv. was published early in the year, and the second and third parts (now ready for issue) were delayed owing to the pressure of work caused by the preparation of the Conifer volume.

The Conifer Conference report, forming vol. xiv. of the Journal, is a work on the publication of which the Society may well be congratulated, and the thanks of all the Fellows are due to those who have so kindly contributed to it, and also especially to those on whom the heavy work of editing the volume has fallen.

The Council wish to repeat verbatim one paragraph of their last year's report, which runs as follows:—

All these conferences and meetings, and especially the work and maintenance of the Chiswick Gardens and the publication of the Journal, have involved the Society in a very large outlay, and the Council take this opportunity of endeavouring to impress upon Fellows the absolute necessity there is for them all individually (as many as have the Society's welfare at heart) to endeavour to secure new Fellows to the Society if its work is not only to be continued at its present standard, but still more so if the ever-opening and extended opportunities of usefulness are to be embraced and accepted. The adoption of £1 ls. as one rate of subscription was, no doubt, a popular movement, but the Council desire to remind the Fellows that such a low rate of Fellowship can only be self-supporting if it draws into the Society a very large number (far

larger than at present exists) of additional Fellows. The Council, therefore, venture to express the hope that every Fellow of the Society will make an endeavour to obtain at least one new Fellow during the present year. A statement of the privileges of Fellows and of the aims and objects of the Society will be found in the Society's arrangements for 1893, page 5.

The following table will show the Society's progress in regard to numerical strength during the past year:—

DEATHS IN 1892.				FELLOWS ELECTED 1892.			
		£	s. d.			£	s. d.
Life Fellows	27	0	0 0	4 Guineas	8	33	12 0
4 guineas	2	8	8 0	2 "	75	157	10 0
2 "	18	37	16 0	1 "	291	305	11 0
1 "	25	26	5 0	Associates	4	2	2 0
	72	£72	9 0	Affiliated Societies	13	15	15 0
					391	£514	10 0
				Deduct loss		236	5 0
				Net Increase in Income	....	£278	5 0
				New Fellows, &c.		391	
				Deduct Resignations and Deaths		185	
				Numerical Increase	..	206	

The most noticeable feature in last year's work, besides the Begonia Conference and the issue of the Conifer volume, has been the promulgation of a scheme for the examination of students and others in the principles and practice of horticulture, and a scheme is on foot for providing scholarships, whereby the most promising students may be enabled to pursue their studies in connection with the Society's Gardens at Chiswick or elsewhere. The first examination was held in the early part of the year at the request of the Surrey County Council, when seventy-two candidates presented themselves, with the result that twelve passed to the satisfaction of the examiners in the higher grade, and seventeen in the lower grade. A second examination will be held in May of this year, when it is proposed to extend it to candidates in all parts of England.

In round numbers £1700 has been expended at Chiswick this year on the general work, and repairs and keeping up of the Gardens. A further sum of about £386 has been laid out in special repairs—viz., in the thorough repainting and repair of the great vinery both inside and out, and in furnishing a new boiler, &c. The receipts from the Gardens by sale of surplus produce amount to £573, making the net cost of the Gardens £1514.

In conjunction with the Lindley Library Trustees, the Society's library has received considerable attention. All serial publications have been kept up to date, a large number of valuable volumes have been bound, and the following new books, amongst others, added to the library—viz.:—

- "Schweizerisches Pflanzen-Idiotikon."
- "Synopsis Muscorum europæorum."
- "Synopsis Filicum."
- "The Uses of Plants."
- "The Narcissus, its History and Culture."
- "The Silva of North America."
- "The British Moss Flora."
- "Stein's Orchideenbuch."
- "Indische Heil und Nutzpflanzen."
- "La Taille des Arbres fruitiers," and many others.

The best thanks of the Society are due to all those who, either at home or abroad, have so kindly and liberally presented books to the Library or plants or seeds to the Gardens. A list of the donors has been prepared, and will be found in the Society's Journal, vol. xv., parts 2 and 3, 1893. The Council also wish to express, in their own name and in that of all Fellows of the Society, their great indebtedness to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the conferences and fortnightly meetings.

The papers read at these meetings, most of which have been already published in the Journal, are as follows:—

- Jan. 12 "Winter Vegetables," Mr. W. Iggulden.
- Mar. 8 "Plants for House Decoration," Mr. John Wills.
- " 22 "The Cultivation of Melons," Mr. C. Ross.
- April 12 "Daffodils," The Rev. G. P. Haydon, M.A.
- " 19 "The English Florists' Tulip," the Rev. F. D. Horner.
- May 3 "Bulbous Irises," Professor Michael Foster, F.R.S.
- " 17 "Hardy Climbers and Creepers," Mr. W. C. Leach.
- June 7 "Summer Pruning and Training of Fruit Trees," Mr. A. Young.
- " 21 "The Management of Trees in Parks and Gardens," Mr. W. T. Thiselton Dyer, C.M.G., &c.
- July 12 "Orchids for a Cool House," the Rev. E. Handley, M.A.
- " 26 "Insect-eating Plants," Mr. A. J. Manda.
- Aug. 9 "Fuchsias," Mr. Geo. Fry.
- Sept. 6 "Root-Pruning," Mr. Geo. Bunyard.
- " 20 "Variation of some Hardy Plants under Cultivation," the Rev. C. Wolley Dod, M.A.
- Oct. 4 "Michaelmas Daisies," Mr. D. Dewar.
- " 18 "Cycads," Mr. W. Carruthers, F.R.S.
- Nov. 1 "Fruit Trees in Pots," Rev. W. Wilks, M.A.
- " 15 "Zonal Pelargoniums for Winter Flowering," Mr. C. Pearson.

The hearty thanks of the Society are due to the Chiswick Board and to all the members of the standing Committees—viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchid, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments; also to the exhibitors who have contributed to so great an extent to produce the valuable results of the various meetings.

The Council have the sad duty of recording the death of seventy-two Fellows during the year, and amongst them they regret to find the names of the Duke of Manchester, the Duke of Marlborough, Earl Denbigh, the Earl of Lichfield, the Marchioness of Waterford, Sir Henry Cotton, Captain Nelson, Mr. C. Sharman, &c.

A scheme for the affiliation of local societies was put forward in 1890. and forty-six local societies have availed themselves of it. The Council express the hope that Fellows will promote the affiliation of societies in their own immediate neighbourhood.

In the spring of the year the Rev. W. Wilks—who has acted as Honorary Secretary of the Society since 1887, and the great value of whose services is well known to the Fellows—requested that he might be relieved of his office. Understanding that he took this step solely on account of his having received an offer of literary work which he did not feel justified in refusing, the Council unanimously decided to

take advantage of the power given in the Charter of making the Secretaryship a salaried office, as it is in the Royal Society, the Linnean, and most other similar bodies. They are glad to be able to say that, under the altered conditions, Mr. Wilks willingly consented to refuse, for the present at least, the lucrative offer that had been made him, and to continue to devote his services to the Society's welfare. A resolution to this effect will be submitted to the annual meeting. This alteration of the Secretary's position created under the Charter a vacancy in the Council.

Besides the great Spring Show in the Temple Gardens, which will be held this year on May 25th and 26th, the Council have decided to hold a Show at Chiswick on July 11th, at which prizes will be offered for local exhibits.

The Council have also entered into an agreement with the Directors of the Royal Agricultural Hall, Islington, to hold a great Autumn Show at that Hall, from August 29th to September 1st, inclusive. A special schedule will be issued in March, and upwards of £400 in prizes, medals, &c., will be offered for fruit, flowers, and vegetables, and for horticultural appliances, machinery fittings and sundries. All articles shown in the latter group will have to be fitted up and in working order from August 24th to September 1st, so that the judges may put them to practical tests.

#### WHAT CONSTITUTES AN AMATEUR?

MR. MOLYNEUX'S definition (page 117) would apply to almost every case, still this has its difficulties. In athletics an amateur may not take a money prize; it would not do in horticultural competitions. And "dealing in horticultural produce" has its loophole. Is parting with your surplus stock of Grapes or wall fruit "dealing in horticultural produce?" Is selling our surplus cut flowers, Orchids, for instance? If it be, I am afraid few of us can escape. Is giving buds or seeds to gardeners, and receiving plants in exchange, "dealing in horticultural produce?"

Further, almost as difficult of definition as amateur is the word gardener. What or who is a gardener or "paid gardener?" Some years ago, a country committee, anxious to get some of the tradespeople in the town to exhibit Chrysanthemums, made four or five classes for "those not employing a regular gardener." "Yes," I remarked, "a very good thing, and I can exhibit in that class." At this there was a loud cry. "Why, you have two men at work." "Yes; one is my groom, who has nothing to do with my Chrysanthemums, and the other man

only does with them exactly what I tell him; in fact, no better than a labourer."

I did not show in those classes, and never intended doing so; but at a large provincial show I did enter in classes for "those not employing a regular gardener." I took a prize in each of the classes, but I cannot say that I think the classes were intended for persons like myself, and I have not repeated the experiment. Seeing that I potted almost every plant, that I stopped them, set the buds, &c., I consider I was my own gardener, and entitled to enter, but I still do not feel that it was a class meant for me. Yet I can also see that against persons employing professed gardeners, one for hothouses, another for Roses, and a third for Chrysanthemums, I have but faint prospects of obtaining any position but at the tail end of the class.

A "paid gardener" should mean a man who from his knowledge can command at least 20s. a week. Again, a person who has a trained gardener in once or twice a week, and follows out his directions, is far better placed than one employing a man regularly, who is yet no professed gardener. This also needs being settled. My own view is just this, that a man who can command his pound a week, or, if going

out by the day, receives 3s. 6d., that man should be considered a professional gardener, and, if employed only once a week, should yet disqualify a person from exhibiting in such restricted classes.—Y. B. A. Z.

### CALLISTACHYS LONGIFOLIA.

A CORRESPONDENT writes:—"I cannot understand why so many of the beautiful hard-wooded plants have been allowed to slip out of cultivation," and adds, "Callistachys longifolia used to be a special favourite of mine, but I have not seen it for years. It should be more generally grown."

We have under the circumstances much pleasure in giving our correspondent another glance at his "special favourite," and agree with him that it ought to be "more generally grown." The accompanying illustration (fig. 26) portrays the flowers and foliage of this somewhat neglected plant, which, as a rule, blooms during the summer. The leaves are lanceolate, mucronate, some 6 inches long, smooth, dark

FIG. 26.—CALLISTACHYS LONGIFOLIA.

green above. The standards of the flowers are yellow, and the wings purple. When properly treated the plants are extremely beautiful, and ought to be more frequently seen in gardens.

### HARDY FRUIT GARDEN.

**Apricots, Peaches, and Nectarines.**—The season is now sufficiently advanced to undertake the pruning and refastening of the trees to the walls. Apricots should be operated upon first, as they are the first of stone fruits to expand their blossoms. They are hardier, too, than Peaches and Nectarines, but not sufficiently so to withstand, without protection, all the rigours of adverse weather after the flowers have expanded. If efficient protection can then be afforded during that critical time, good crops of fruit will be secured. The same applies to Peaches and Nectarines. On well-managed wall trees the principal pruning is done immediately after the fruit is gathered. That practice is, however, not general owing to various reasons, and there is often much to be done to trees at this season.

**Main Branches.**—It is assumed that the trees will, in order to prevent the buds swelling prematurely, have been loosened from immediate contact with the walls during the winter. It is important that the principal branches retained be in a healthy and vigorous condition, or gaps may occur in the framework of the trees which will spoil their appearance. Apricots are subject to the sudden dying away of branches, but not necessarily so when good culture and proper systems of pruning are accorded them at every period of growth. Any principal or subsidiary branches that exhibit any loss of vigour remove entirely before commencing to re-arrange. Branches of medium strength are the most satisfactory. The main branches should be spaced out to equally cover the wall, the subsidiary ones being allotted positions accordingly, so as to leave sufficient room for the disposal of the bearing shoots.

**Mode of Bearing.**—There are three distinct methods by which Apricot trees bear fruit. The most general method of culture is the training and laying in yearly of a number of the previous year's shoots. The finest fruit is borne on these. After the fruit is gathered the bearing parts are cut out, their places being taken by succession shoots trained for that purpose. In addition to these, however, a number of shoots are produced either badly placed for laying in, or for which no room can be found. Many growths are rubbed off by disbudding or cut off annually in the early summer, but some are retained. Those not wanted for laying in as succession shoots are shortened when they have developed three or four good leaves, resulting growths that push afterwards being pinched to one leaf. The growths thus managed in summer and shortened to a few buds in autumn or winter develop in time into spurs. These, not too freely encouraged so as to crowd the trees, nor allowed to lengthen and become too large, will, when a few years old, produce fruit, furnishing the wall where it might otherwise be bare. Besides the last-mentioned there are the natural spurs, which Apricots produce freely. They are preferable to those produced by pinching, as they are closer to the wall, need less management, and are safer from injury in bad weather. Peaches and Nectarines will also fruit on spurs, but as a rule young wood annually laid in is the best.

**Management of Young Wood.**—With free exposure to light and air in the autumn, and a position away from direct contact with wall surfaces in winter, young wood becomes thoroughly well ripened. It then produces strong properly constructed blossom buds along the entire length of each shoot, interspersed with wood buds, the latter sometimes solitary, at others in company with one, two, or a cluster of fruit buds. It is generally necessary to shorten the bearing shoots or young wood when laying it in, doing so more or less according to their vigour, the position of wood buds, or the ripened condition of the shoots. It is useless to shorten a bearing shoot to a fruit bud, as extension cannot take place from it, but must proceed from a wood bud. It is necessary to have a growing shoot above the fruiting portion of a young branch, in order to attract sap to the fruit. Shoots immature at the tips shorten back to ripe wood, selecting a triple bud, and cut above that. The shoots retained should be from a foot to 15 inches in length, but if greater lengths of ripened wood are available, and can be accommodated without crowding, secure them.

**Cleansing Walls and Trees.**—Before the trees are again permanently secured in position, take precautions that the branches are perfectly free from the eggs of insects, the crevices and crannies of the rougher portions of the bark often affording secure hiding places for them. It is the same with the walls. Old nail holes and spaces between the courses of bricks occasioned by the falling away of mortar, are frequently full of active and inactive insect life. Such spaces ought to be filled either with mortar or cement, but where nails have to be driven in the latter should not be used. Afterwards wash the whole wall surface with a strong solution of Gishurst compound, 8 ozs. to the gallon, or some other of the advertised insecticides. Paint the trees with a solution of less strength except for the rougher parts of the tree, such as the main stems and branches. Brush the mixture well into every angle, crevice, and corner of the wood, taking care not to dislocate or injure the buds. To facilitate the operation of applying the solution, slightly colour it with soot and sulphur.

**Nailing and Training.**—In refixing the trees secure the main branches firmly and dispose the others equally, leaving space for the bearing shoots to be trained in 4 or 5 inches distance from

each other. From the base of each young shoot, it must be borne in mind, a succession growth has to be selected and trained in during the summer. If, therefore, the young wood is trained in too closely there will not be room for successional growths. Use clean, strong shreds and good nails, but as few as possible consistent with security. See that the shreds do not close round the wood, especially the young wood, too tightly, nor allow nails to press against the bark to injure it and cause gumming.

**Top-dressing the Borders.**—Should the surface soil of the borders be exhausted, and few fibrous roots to be found, clear away the old soil until some roots are discovered, and add fresh compost, sweet loam containing some pulverised lime scraps and charred refuse. Too rich compost is not desirable, but if the trees are weakly a good soaking of liquid manure would be beneficial. Ascertain first, however, that the border is not dry below; because, if so, clear water should first be given. This would moisten the soil and prepare it for enrichment with something stronger and more stimulating.

#### FRUIT FORCING.

**Figs.**—*Earliest Trees in Pots.*—With a steady bottom heat of 70° to 75° about the pots the roots are now very active, and the points of the rootlets showing at the surface is a clear indication of their eagerness for further supplies of nourishment. To supply that turves 3 inches thick and 1 foot long may be placed around the rims of the pots, extending a couple of inches inside the rim, and the other part of the turf projecting over may be turned down by the side of the pot, closely placing fermenting material against it. This will leave a receptacle around the stem for top-dressings of partially decayed lumpy manure, and the roots will permeate the turf and pass along it over the pot rims into the fermenting material. Where there is not a fermenting bed hoops made of lead or zinc 4 inches deep should be placed inside the rims of the pots and occasional surface dressings given. Liquid manure in a tepid state may also be given in sufficient quantities to pass through to the drainage as required. Trees carrying full crops will require frequent supplies, and a varied dietary is more beneficial than always adhering to one kind of nourishment. Nitrate of calcium is the essential food of the Fig, but it must only be used in a weak state, say 1 oz. to 8 gallons of water regularly, or 1 oz. to 4 gallons of water when given occasionally. Liquid manure from stables and manure yard tanks should be weak, pouring it on the turves as well as in the pots. Regularity in watering is a great point in the cultivation of Figs in pots.

Keep the atmosphere in a genial condition by syringing twice a day when the weather is fine, and by damping the surface of the bed, walls, and paths when dull. Maintain a night temperature of 60°, 5° less on cold nights, 60° to 65° by day artificially when cold, and 10° to 15° rise with gleams of sun. Ventilate a little at 70°, keep at 75° to 80° through the day with sun heat, and close early so as to run up to 85° or 90°. Stop and tie the growths as they advance, keeping them rather thin. Figs, to have flavour and colour, must be fully exposed to light and have a free circulation of air.

**Early-forced Fig Trees in Borders.**—Those started early in January must be attended to in disbudding and stopping, leaving no more shoots than are required for extension, and a due supply of successional bearing shoots. Extension shoots need no stopping, nor do successional growths when the wood is sturdy, short-jointed, and fruitful. All the growths must be thinly and evenly disposed, stopping spur-shoots at the fifth or sixth leaf; but it is not advisable to encourage too many of these, as the best fruit is borne on the extension shoots, yet spurs give good results in the second crop. Mulch the borders with a rich compost as the roots rise to the surface, and supply tepid liquid manure freely. An occasional dressing of some approved advertised fertiliser, applied according to the instructions, accelerates root activity, as well as supplies nourishment, provided the surface of the border is kept properly moist. The temperature and atmospheric moisture should be similar to that advised for pot trees.

**Late Houses.**—If these are expected to supply two crops of fruit the trees must be pruned and cleansed, and the houses started not later than the beginning of next month. Unheated houses are only fitted for producing one crop of fruit in August and September. The trees should now have the protection removed, be pruned and dressed, keeping the house as cool as possible so that they may start naturally. In unheated houses the growths should be kept thin, so that the young shoots may be firm, short-jointed, and with judicious management well matured, otherwise satisfactory crops are uncertain.

**Pines.**—*Starting Shoots.*—A batch of these will have to be started about the beginning of March to provide plants to give a succession of fruit from next December onwards. Attend, therefore, to the preparation of a fermenting bed in some close structure to maintain a bottom heat of 85° to 90° near the surface, and with means of securing a temperature of 55° to 65° with regularity. Attention must also be given to the preparation of the soil for potting, having it under cover to become warm and properly fit for use.

**Plants Started for Fruit in December.**—Those selected early in that month and advanced by an increased temperature are now showing fruit. As it is desirable to forward the ripening of the fruit of these plants as much as possible the temperature should be maintained at 65° to 70° at night, 5° to 10° more under favourable external conditions in the daytime, ventilating at 80°, allowing an advance to 85°, and closing the house at that temperature so as to husband the sun heat. The plants, now the fruit is advancing, will require more water at the roots, examining them once a week and affording a supply to those in need, as with more light and heat the demand increases.

**Recently Started Plants**—This batch being intended to succeed those just named, the plants need not be hurried, but allowed to come on gradually in a temperature of 65° at night and 70° by day artificially, ventilating at 75° and closing at 80°. Due supplies of water should be given at the roots, but only when required, and always of a stimulating nature, say 1 lb. of guano to 20 gallons of water.

**Peaches and Nectarines.**—*Earliest House.*—A steady progressive course is the safest, maintaining a night temperature of 50° to 55° in severe weather, and not more than 5° higher when the weather is mild, 60° to 65° by day artificially, and 5° to 10° more with gleams of sun. Ventilate freely under favourable conditions, admitting a little air at 60°, so as to insure a change of atmosphere. Regulate the growth by disbudding; when strong the whole of the foreright shoots may be taken off at once, and some of the side shoots on the extensions be pinched back to form spurs. On shoots, however, that will be removed after the fruit is gathered the best break from the base and another above the fruit only must be retained. Give the basal growths room for extension and full exposure to light, and pinch the shoot reserved on a level with or above the fruit to two or three leaves.

**Second House.**—Trees started at the new year and having previously been forced from that date have set the fruit, but those forced early for the first time are setting, and therefore daily resort to careful fertilisation. When the fruits are all set, syringe with tepid water, which will soon clear them of the remains of the flowers. Avoid, however, excessive syringing, as it induces a soft growth. The night temperature should be kept at 50°; 55° by day, and 5° to 10° advance from sun heat, ventilating freely whenever the weather is favourable. Defer disbudding until the fruit is fairly swelling, and proceed carefully and gradually, but follow it up when commenced, not deferring it so that large reductions of growth must be made at once. Checks of any kind are usually disastrous to the fruit. Supply water to inside borders so as to keep the soil in a healthfully moist state, but do not make it sodden and sour by needless supplies.

**Third House.**—The trees started at the beginning of this month have the flowers advanced, and a close inspection should be made for aphides, or as a precautionary measure fumigate, having the trees dry, and repeating it on alternate evenings. Take care not to give an overdose, as that may discolour the corollas, and the blooms so damaged seldom set satisfactorily. When the anthers show clear of the petals, cease syringing the trees, yet maintain a genial atmosphere by damping available surfaces in the morning and afternoon. Maintain a day temperature of 50° by artificial means, 40° to 45° at night suffice by that agency. Ventilate at 55°, allow an advance to 60° or 65° from sun heat, with a free circulation of air. Make sure that there is not a deficiency of moisture in the inside border by examining it occasionally, and when necessary afford a thorough supply of water.

**Late Houses.**—Keep these freely ventilated by night and day, except where the buds are advanced in swelling and when frost prevails. Houses from which the roof lights have been withdrawn need not have them replaced until the buds commence swelling and the most forward blossoms are showing colour. Where the roof lights are fixed they may be covered with mats on sunny days so as to retard the blossoming, and take care that the roots of the trees are kept properly moist. Neglect of due moisture at the roots often causes many of the buds to fall.

#### PLANT HOUSES.

**Acalyphas.**—Plants used in the conservatory and afterwards cut back and placed in heat will have plenty of shoots to provide cuttings. These may be taken off and inserted in thumb pots in sandy soil. Give a good watering and plunge the pots in the propagating frame. The cuttings root freely and quickly if kept close. Plants with good heads that have become bare at the base may be notched and moss bound round the wounds. If these plants are kept close they will soon emit roots from the stem, and will be ready for taking off and placing singly in pots. Plants raised from tops should, if well cared for, make good specimens with bold foliage at the base.

**Euphorbias.**—Those plants that have done flowering should be kept on the dry side at their roots in a temperature of 50° to ensure a short rest before again starting them into growth to yield cuttings. Poinsettias may be subjected to the same treatment.

**Gardenias.**—Young plants rooted in July or August may be placed into 5-inch pots. If possible plunge the plants where they can enjoy a slight bottom heat. When once they start into growth they will push up freely from the base and make excellent plants for flowering in one season. Plants that are swelling their flower buds push on in brisk heat. Others that have their flower buds just set must not be checked by keeping them in too low a temperature by giving them cold water, over-feeding, or the use of strong insecticides, or the flower buds will be deformed. Those plants that were cut back late and are not going to flower may have the points removed and then started into growth with the young stock.

**Asparagus plumosus.**—Cuttings may be inserted in thumb pots; one joint with a small frond attached will be ample. Plunge the pots in the propagating frame. During the summer they will make good plants for table decoration and other purposes. When larger plants are needed put some of those raised last year from cuttings into 7-inch pots. *A. plumosus nana* must be increased by division. Select a plant or plants that have made a number of crowns and not started to run. These are the best for propagating purposes, and every piece with an eye will make a plant. When once established this plant does much better in a cool house than in heat, and is rarely attacked by insects unless it is aphides.

**Marantas.**—These should be repotted where they need it, as they invariably do best in fresh soil. If the plants are potted at once and plunged in bottom heat they will become established before the sun gains much power. These plants cannot endure bright sunshine, but they delight in a close moist shady atmosphere. Where an increase in the stock is needed the plants should be divided. Do not overpot them. Use a compost of good fibry loam, one part leaf mould, one-seventh of decayed manure and sand; charcoal in lumps may also be added. Some of the large kinds do best in a rough compost of fibry loam from which the small particles of soil have been removed, rough peat, sand, and charcoal.

## THE BEE-KEEPER.

### APIARIAN NOTES.

"HOPE springs eternal" in the husbandman's breast, whether he be fruit grower, farmer, gardener, or bee-keeper. The past may have been fruitful in losses, but as spring comes round hope revives, and the newly turned up fresh soil adds renewed animation to the sons of toil. With the bee-keeper joys are increased by the appearance of flowers on every side, the singing of birds, and the hum of the honey bee.

Our bees searched for pollen on the first day of February, but as yet (the 9th) none has been gathered, but it cannot be delayed long now. In order to keep the bees near the apiary to prevent loss, they will be supplied with peameal, and water troughs in sunny nooks. A terra cotta pipe a foot or more in diameter, closed at one end, is a suitable place for the former supply, and a cylindrical vessel filled to within a few inches of the top with water covered with granulated cork is good for bees. Honey and peameal mixed to a thin paste, and put into a scoop, is also good for them.

### FEEDING.

Hives suspected of being short of stores before May will, whenever the weather is calm and serene, be supplied with a few pounds of food from below. The crown of the hive at this season should not be opened, as it induces cold, and the bees to leave the cluster where they are most required to keep up the heat for the gradual development of the brood. When checked they creep out of their cells in a mutilated form. Beyond these operations all my hives will remain as they were arranged in the autumn until the deposition of young queens take place after swarming, or the application of supers some time in June.

In places where the only honey flow comes early in the season, feeding a little more liberally will insure the greater number of eggs being brought forward; but in the majority of cases no advantage is gained. Utilising the brood, or portion of it, from another hive on the two-queen principle gives early and strong stocks suitable for gathering the maximum yield of honey in the shortest period.

### OLD BEES FEEDING YOUNG ONES.

Apropos of field bees feeding youthful bees inside the hive, it is well to remember that a full colony requires a large quantity of water for the internal economy of the hive in brood-rearing, sealing, wax secretion, and the building or alteration of the comb. Water for some of these purposes is given by the adult bees to the younger ones, probably because it has risen to a higher temperature in the stomach of the adult bee, and is then more suitable for the purpose than if it was several degrees lower; besides, who knows but the water, in contact with the stomach of the bee, acquires a chemical change suitable for certain purposes within the hive?

### BEES AND ELECTRICITY.

It is now many years since I first noticed several phenomena regarding bees and electricity. I wish to go a little further, and ask those who are able to do so to try a few experiments with bees as to their electrifying power during the present year. I made a number of experiments with a magnetic needle; in every case the needle was affected out of its true course when changed from the one side of the bees to the other. I will repeat the experiment when I am certain there is nothing about but bees to affect the movement.—A LANARKSHIRE BEE-KEEPER.

### TOMTITS AND BEES.

I saw in the Journal of January 5th (page 18) an interesting article on "Tits and their Habits," so I thought that an extract from my manuscript on bees would interest your readers. On November 30th, 1872, I saw on one of my bee-benches a number of wings, legs, stings, and outside scales of the bodies of bees. I soon said, "The Tomtit (*Parus cœruleus*) has been busy here." I had not noticed or seen it before that year, but about four o'clock I saw

three tomtits eating my bees. One of them I watched, and saw him fly down on to the alighting board of one of the hives. He began tapping it with his bill. Shortly a bee came out to see who was there, and was immediately snapped up by the tomtit, which flew with it into an Apple tree near the hive. He then beat the bee against the bough of the tree, on which he stood until it was killed. Then the tomtit with its right foot and beak pulled the bee's wings, legs, sting, and head off, letting the rejected parts fall to the ground, and it then ate the dainty parts of the bee. The tomtit was soon down on the alighting board of the hive again; tap, tap, tap, and another bee came out to see who was there. Then the same process was repeated. I saw him take five bees in this way in seven minutes, when I could stand it no longer, so I frightened the tomtit away, as I was afraid he might have the nightmare with eating such an enormous supper.

The tomtits were eating my bees again before ten o'clock the next morning. So I brought out my gun and shot three of them, and on opening their craws I found them nearly filled with bees—one head, antennæ, and tongue complete. This bird must have been very hungry, as they generally reject the head. I found no wings, legs, or stings in the craws. It grieved me very much to have to kill these useful, beautiful, and interesting birds, but it required patience to see my pets—the bees—so mercilessly destroyed.

Your correspondent is quite correct. The tomtit does no harm to fruit buds or to the bees in summer, there being at that time such an abundance of insect food which the tomtit prefers. It is only when its natural food fails that it attacks the bee hives.—WM. CARR, *Newton Heath Apiary, Manchester.*

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Dry Fruit Borders** (*J. Dobbs*).—You have undoubtedly done right in watering the borders. No greater mistake can be made than permitting Vine and Peach borders to become distinctly dry in the winter. You would have done still better in giving liquid manure copiously in the autumn. We conceive it impossible for either the Vines and Peach trees to long continue, even in a small degree, satisfactory in the too shallow borders under the alternative system of management indicated in your letter.

**Moss on Lawn** (*Hants*).—After all the efforts you have made to eradicate the moss, and the more you do the more it grows, we conclude the lawn requires draining. If stagnant water lodges in the soil moss is sure to be troublesome. A free dressing of lime, sifted soil, and wood ashes in equal parts might do good, and a subsequent application of bonemeal at the rate of 2 or 3 ozs. to the square yard. Much more good might also be done if drains were cut and pipes laid carefully 2 feet deep and 5 yards apart, with proper fall and outlets into a lower drain for the escape of the water.

**Renewing the Soil for Tomatoes** (*N. L.*).—It is much the best plan to renew the soil every year, having it about 1 foot deep over good drainage, taking the whole out and supplying fresh in its place. This need not be an expensive affair, for the top spit of good garden soil that will grow Potatoes well will answer for Tomatoes. We advise that plan—make an exchange of the top spit in the house for the top spit of good soil outdoors, with a judicious application of artificial manure. Dwarf Kidney Beans would only be profitable if distinctly early. Ne Plus Ultra is an excellent variety, but the danger is that they will introduce red spider, and that is a fearful pest on Tomatoes and Vines.

**Distance of Vines for Profit** (*N. L.*).—This is a vexed question, some preferring close and others wide planting. When the free-bearing varieties are grown, such as Black Hamburgh, the Vines are usually planted 3 feet apart as you propose, and double the crop is had from the first that would be obtained were only half the Vines planted. They are cropped the year after planting, and each Vine is taxed to its fullest capacity consistent with perfect finish in the fruit. This is a difficult point to determine, and requires a perfect knowledge of

the bearing power of the Vines. This heavy cropping does not last long. Several growers find it profitable to occupy the space quickly, crop the Vines heavily, and when they are exhausted root them out and plant young Vines, or cut away the old rods and replace them with young from the base. The plan seems to be what you require—the fullest supply of Grapes of marketing quality from the least space in the shortest time; therefore another Vine may be planted midway of the distance between the existing ones, so that they will be 3 feet apart; but you must not expect that part of the Vines on the back wall to produce satisfactory Grapes after the roof two-thirds down is occupied with rods 3 feet asunder.

**Grubs in Marguerite Leaves (F. D.).**—The leaf-mining insect is the larva of a small fly (Tephrites) similar to, if not identical with, the Celery fly which punctures the leaves and deposits eggs in them, these hatching into maggots that eat out this substance, often ruining the plants. The Celery fly can be prevented doing material injury by syringing the plants with a solution of petroleum and softsoap, 2 ozs. of the soap and a lump of soda being dissolved in a gallon of boiling water, stirring in very briskly while hot half a wineglassful, or a little more, of ordinary petroleum, or paraffin as it is incorrectly called, such as is burned in lamps. It should be applied to the plants in the evening. We have known it to destroy the maggots in the leaves. You can try the experiment of dipping a plant in the solution and noting the effects. You might also try lemon oil, using it according to the instructions supplied by the vendors.

**Mushrooms in Summer (Amateur).**—We gather from your letter that you desire to grow Mushrooms outdoors in summer. For that purpose a cool place is essential. A grower of our acquaintance digs a trench of the requisite width on the north side of a wall, fills it with suitable manure pressed down in the usual manner, sloping the surface up to the wall, casing with soil, covering and keep all moist, and he has excellent crops. In the absence of a position of that kind choose the coolest you have, and under and behind evergreens would be likely to answer very well. We have had good crops in a cool heavily shaded orchard in the summer. The less grass the horses have the better for the purpose in view, though we do not think you ought to fail under the circumstances you describe. You may mix one-third of Beech or Oak leaves with the manure, taking care the whole mass is uniformly moist, not over-fermented when used, and then made very firm. Peat moss, after being used in stables, may be mixed with the other materials, but excellent crops of Mushrooms have been grown from it without any admixture beyond a little loam. It cannot be so well formed into ridges as manure consisting largely of decaying straw. You had better perhaps make the beds flat or nearly so, and cover them with shutters or anything that will throw off heavy rains. Narrow ridges are apt to get too dry in summer, and if you make a bed on the level of the ground, supporting with boards, care will be necessary not to let it get too dry, especially round the sides.

**Wet Tennis Lawn (L. M.).**—The half of the lawn which is so wet and unsatisfactory is obviously the result of bad workmanship. In levelling, some of the clay should have been taken out and a layer of porous soil added equal in thickness to that under the other half of the turf that is good. Drains in such a case are of small service, as the surface water cannot pass through the clay above them. Where drains are operative it is mainly by subsoil water rising upwards, then passing away through them, the level of the pipes being what is termed the water table, which but for them would be higher and the land might be swamped. Water does not pass downwards and directly into drains, but to the water table, hence pipes a foot below the surface may be "dry," while others 2 or 3 feet below them may "run" freely. The turf should be taken off, some of the clay removed, a thick layer of soil and ashes spread on, firmed, and the turf relaid. Until that is done the bad half of the lawn cannot be made equal to the other.

**Artificial Manure for Tomatoes (X. Y. Z.).**—There is little doubt that the heavy dressing of farmyard or stable manure accelerates, if not induces, the development of the worst forms of Tomato diseases. 1, That in the leaves, fruits, and stems the Potato fungus (Phytophthora infestans); 2, Root disease caused by eel-worms (Tylenchus devastatrix). Artificial manures act in the opposite direction by strengthening the epidermal and structural tissues of the plants, and are especially valuable where the soil is rich in humus, or where the ground has been heavily manured or contains much vegetable matter, as turf. The following usually gives good results with both Potatoes and Tomatoes: Bone superphosphate 2 lbs., nitrate of soda 1 lb., kainit 1 lb., sulphate of iron, 2½ oz. mixed and applied at the rate of 2 ozs. per square yard. At that rate it is an excellent auxiliary to Potato land which has been manured with farmyard manure, applying it at the time of planting the tubers, and it may be used for Tomatoes when planting. It will not, however, do to follow on with the mixture as a top-dressing through the season on account of the chlorides which the kainit contains, and about three applications will be sufficient, say at planting (now or soon), again in six weeks, and a third dressing at a similar interval, or three only during the season. Midway of these periods you may use the following: Bone superphosphate 3 lbs., nitrate of potash 2 lbs., sulphate of lime 1 lb.; mix and apply at the rate of 2 ozs. per square yard, or, if the plants are weak and heavily cropped, double the quantity of this mixture may be used, but not of that which contains kainit. The last named mixture (not kainit) may be used exclusively through the season at intervals of about three weeks, taking care to have the saltpetre (nitrate of potash) finely powdered, otherwise it may injure the roots it comes into contact with. Similar remarks apply to nitrate of soda.

## SPRING CROPPING.

In drilling spring corn the advantage of "clean" land must not be forgotten. With it we can distribute the seed in the best way; without it the seed must be confined to drills far enough apart to admit of the use of both horse and hand hoes. The best way of sowing is to drill half the usual quantity of seed and then to cross-drill the other half—i.e., across the first drills at right angles to them. By this method we obtain the best possible plant over the entire surface of the field, the evenness and regularity of which is altogether superior to that from broadcast sowing, which depends so much upon the skill of the sower, and in any case can never be quite regular. Thick

*versus* thin sowing has been much discussed; each plan has its advocates, but we think a medium course usually answers best. The four points of most importance are clean well-tilled soil, thorough fertility, good seed, and careful sowing.

If the manure application has been left till now, then it is certain that chemical manures must be used. Of these, to have a compound manure in which all the essential elements of plant food are present, take per acre  $1\frac{1}{4}$  cwt. nitrate of soda, 3 cwt. mineral superphosphate,  $\frac{1}{2}$  cwt. steamed bone flour,  $\frac{1}{2}$  cwt. muriate of potash. This is a safe and perfect manure, more perhaps than is necessary; the only thing which may be dispensed with, however, is the potash for clay or heavy land, which usually contains enough of it. In the preparation of formula we have to make sure that there is enough of each of the indispensable elements of plant food—*i.e.*, nitrogen, potash, and phosphoric acid. Without analysis it is not easy to say if potash is required. Crops tell quickly enough, and we strongly advise our readers to watch growth closely in the coming spring and summer. If the spring corn is seen to be of a pale green or yellowish hue, it is probably owing to a want of potash; if it is certain that the soil is well drained, then it is positive that potash is wanted. If more potash or phosphates are used than is requisite for the crop or crops of the current year, we know that the soil is able to hold them in suspension for the benefit of other crops; but if we use a superabundance of nitrogen that is waste, because it is so liable to be washed down to the drains by rain water. Even in this matter we derive some comfort from the fact of an equivalent of nitrogen entering the soil from the air. By all means endeavour to avoid the wasteful use of manurial salts, but in any case it is better to err on the side of too much than too little.

It will thus be obvious to our readers that we regard the Oat crop, whether it be spring or autumn sown, as now being one of the most important and profitable crops grown upon British farms. It can be turned to account in so many ways, for horses, cows, store cattle, sheep, pigs, poultry; all like it, all thrive upon it, and any surplus is always to be sold at a profit, if only it is well grown. That is the point; strive to have only the best sorts on the farm, have them so well managed that your samples are of the best, and there will never be any difficulty about a market. As silage it is preferable to roots, being decidedly more nourishing, much less expensive to cultivate and to store; it keeps good twice as long as roots, and there is none of the uncertainty about it that there always is with roots. How frequently do we have to sow the same field of Swedes a second time owing to loss of plant from drought or insects! Then, too, the outlay for repeated hoeings, clearing, carting, storing, and slicing, is in the aggregate much higher than when silage is used. We press this matter upon the attention of all farmers as being one of several where reform means profit instead of loss. We have the highest authority in support of our advocacy of this change, as well as the dictates of prudence and common sense. Much Wheat straw has been cut into chaff for feeding cattle, and cows too, this winter, and though it is thus "chopped" to good purpose it must be regarded as inferior to Oat straw as food, and very much inferior to Oat silage. Of course there always must be a certain quantity of Wheat grown in home farms for flour, and for a supply of straw for the hunting and carriage horse stables, but that is a matter of detail, and does not affect the general question of farming economy. The general want of farmers now is crops that pay; certainly the Oat crop is one of them, and we shall do well now to consider advantages so possible, reform so profitable, and to make a radical change in a system of cropping which insists upon the persistent cultivation of crops from custom only.

#### WORK ON THE HOME FARM.

Very trying has the weather been for young weakly lambs. High wind, with frequent showers of cold rain and sleet, is a correct record of the weather day after day since writing our last note. Greatly do we regret saying that we have seen numbers of lambs out with the ewes in

the open, cowering under the cold blasts. Losses from such foolish exposure are a certainty; yet they are easily avoided by keeping the whole of them in a yard or fold, and in trough feeding for ewes, silage, chaff, pea straw in racks, some crushed oats, and a few lumps of rock salt suffice for all the requirements of the ewes. We give them no meadow hay; that is reserved for the dairy cows. Of course the shepherds ask for hay, and insist upon it as a necessity for the ewes, but so long as we have ample supplies of silage, with Pea and Oat straw, or even Barley straw, not a truss of hay do the sheep have, simply because they do not require it. Our dietary for the ewes is bountiful enough. They must be fed well if we would have the lambs well nourished and high condition sustained in the ewes; with this there must be shelter.

Losses of ewes and lambs from negligence either in feeding or in sheltering, or in both, are unpardonable. To say that a due provision of yards and folds for very large flocks is impossible is mere nonsense. If a man can afford to hire a grazing farm of two or three thousand acres, he should insist upon a reasonable provision of enclosures and hovels by the landlord, and do his part in the construction of temporary folds. To make the farm self-supporting preference is given to home grown food, but where circumstances justify the purchase of some food, let it be done. There is no profit possible now in half-fed animals. Lambs must be well fed from birth; they can then always be disposed of to advantage when they have served their turn upon the land.

Folding of hoggets and draft ewes upon poor upland pasture has gone steadily on all the winter, the snow never having been too deep for this work. The sheep as they become fat are gradually sold, and sold profitably too, and the pasture is so thoroughly enriched as to make plenty of rich herbage a certainty in the coming summer and autumn. Advantage was taken of low prices in the autumn to purchase sound store sheep largely for this important work of soil enrichment by means of judicious sheep folding.

FARMERY. — Mr. S. Nicholls, F.E.C.E., Albert Bridge, Battersea, sends us a circular of a very optimistic nature, announcing that he proposes to hold a consultation meeting at St. Martin's Town Hall, Charing Cross, W.C., on Tuesday afternoon, February 28th. Among other things he says:—"That meeting, *per se*, is intended to be quite unique in its character and procedure, and if possible, to be made profitable for the purpose of immediately promoting parochial honeypots and "farmery" combinations. Therefore I am wishful to meet, and be met, with kindness and courtesy by practically thoughtful landowners, farmers, clergymen, engineers, and mechanics having had some experience of agriculture; grist millers, chefs, and cooks (British) of either sex, and more particularly young men and women possessing natural gifts for material conception and constructive genius, with a view to qualify for 'farmery' duties, and thus become, as His late Royal Highness Prince Albert so aptly put it, princes and princesses amongst their country men and women." Then Mr. Nicholls makes the startling assertion that "Farm workmen could easily earn from £3 to £5 per week, and pile up mighty fortunes for their employers under parochial farmery methods of procedure."

#### OUR LETTER BOX.

**Poultry Farming (S. B.).**—Poultry farming pure and simple has never yet paid in this country, but combined with gardening, fruit growing, and dairying, it will pay its way well. Like every other business, poultry keeping must be learned, and you can only acquire the knowledge by starting with a few birds and carefully studying them, then as your knowledge increases so you can extend your operations.

#### REMARKS.

- 5th.—Bright and sunny almost throughout.  
6th.—Fog early, dense from 9 to 10 A.M.; bright sunshine from 10.3 A.M.  
7th.—A little rain early; unbroken sunshine after 9.30 A.M.  
8th.—Heavy rain at 5.30 A.M., then overcast, but clearing after 10 A.M.; occasional sun from 11 A.M. and continuous bright sun in afternoon.  
9th.—Fair morning, with occasional sunshine early; almost continuous rain from 1.30 P.M., and gale at night.  
10th.—Gale with showers early; alternate sunshine and showers after 10.30 A.M.; clear night.  
11th.—Very wet from 8.30 to 11 A.M., then gleams of sunshine till noon, and generally overcast after.  
Not so warm as the previous week, but temperature still above the average.  
—G. J. SYMONS.

FOR some time past more than ordinary interest has been taken in the National Chrysanthemum Society, owing primarily, perhaps, to the opinions expressed by various correspondents in these columns. As the time for the annual general meeting of the members drew near this interest was considerably augmented, because it was known that at least one proposition regarding the adoption of a new rule, calculated to evoke much discussion, would be brought forward. Combining these and other items now known to most of our readers, many persons anticipated an unusually enthusiastic gathering, and as far as the audience was concerned, the most pessimistic attendant could not possibly have cause for complaint. The room, by no means a small one, was well filled, and whilst "waiting for the fray" a thrill of excitement doubtless ran through the veins of those most closely connected with the Society. But withal the meeting in certain respects was, no doubt, disappointing to some of the members. If we except one or two discordant notes which were struck, it was an ordinary, remarkably well conducted and rather quiet gathering of Chrysanthemum growers and admirers. It was nothing more, nothing less; and those who came full of vigour, and with more than a usual amount of buoyancy, expecting to hear eloquent expatiations and witness a "wordy war" were, as we have said, doomed to disappointment. True, many points were discussed, and consequently a little dissension arose, but beyond that nothing of an exciting nature occurred.

As signified elsewhere in the present issue, the annual report of the Committee gave general satisfaction, and from it we gather that the National Chrysanthemum Society, as far as numerical strength goes, is in a flourishing condition. There are at present 620 members on the books, no less than 73 joining during the past year. Of affiliated societies there are 100, and these facts, in conjunction with the work accomplished during 1892, are sufficient to give the surface a gilded appearance. But there is another side to the matter, and when the financial statement showed a balance of only 5s. 4d. to the good a murmur could be heard amongst the members. The receipts during the year amounted to upwards of £940, and the expenditure, as the cash statement showed, corresponded, leaving a very small balance in hand. This, too, notwithstanding, in the words of the Chairman, "a large accession of members and affiliated societies, distinctly attributable to the correspondence that has been going on in the *Journal of Horticulture*." This statement gives us more satisfaction than surprise, and proves that criticism, properly conducted, is beneficial. If it would assist the Society in obtaining still more members, and in collecting the subscriptions that are in arrears, we shall have pleasure in throwing our columns open for further correspondence. We should like very much to be able to record a better state of affairs as regards the present financial position of the Society. The Auditors, gentlemen of the highest standing, bore testimony to the able manner in which the vouchers had been prepared for them, and we have reason to believe that economy in the management has been strictly considered by the Executive. Still, as the Treasurer pointed out in commenting on the subject, it is deplorable that the balance is "only 5s. 4d." "The reserve fund," said Mr. Starling, "has not been kept up as

it should have been by a national Society." "Only 5s. 4d.," repeated the Treasurer; "is that a good position for such a Society to be in?" and albeit the bright picture which Mr. E. C. Jukes endeavoured to draw in referring to the arrears of subscriptions, a gloom for the time being appeared to hang over the meeting. Such is the position of the N.C.S. to-day. Let us hope it will, during the current year, rise to that eminence which the cause deserves, and secure the support of every Chrysanthemum grower in the country.

Relative to the infusion of "country blood" into the management of the Society, some points that could not be other than interesting to a casual observer arose, and particularly so prior to the election of the Committee. As has been discussed in this *Journal*, there is a desire amongst country members to share in the management, and all things considered this is a right and just claim. Several growers resident in the country were therefore nominated for election, but amongst such a strong metropolitan force it could hardly be expected that they would be successful in securing a place. Mr. Goodacre of Elvaston Castle, who was unable to be present, sent a telegram to the Secretary previous to the meeting suggesting the nomination of "some good growers, such as Messrs. W. Mease, P. Blair, G. Woodgate, and J. Lambert." In reading the telegram, however, Mr. Dean remarked that "Mr. Goodacre had written one or two rather warm letters in the *Journal of Horticulture*," and it was the opinion of a prominent member that such an announcement prejudiced many of the electors present. A similar instance occurred on the nomination of Mr. C. E. Pearson of Chilwell. At the election Mr. Blair secured six, Mr. Lambert three, Mr. Woodgate eleven, and Mr. Pearson fourteen votes; Mr. Mease is not a member, and his name was, therefore, withdrawn. Considering the fact that there were nearly a hundred present the results as to the votes accorded these few country members are significant. Apart from this, the system of electing is not exactly satisfactory, and we concur with Mr. W. H. Fowler that another method should be adopted. In accordance with the rules of the Society, no member is allowed to vote for more than twelve candidates, and therefore when this is done by simply showing hands there is no means of checking the electors if a large number of would-be committeemen are nominated. Nor is this all. Under the present system it is just possible that the names of twelve of the most popular candidates are read out, and these men duly elected before the remaining—the less popular—members are mentioned. Mr. Fowler suggested electing the Committee by ballot, which should be done, and we trust that the method will be adopted.

The feature of the meeting, however, was the attempt made by Mr. Addison to incorporate a new rule among the existing ones of the Society. This was the outcome of the "rather warm" letters that have been published in our pages, and was to the effect that "members guilty of dishonourable conduct, or conduct likely to bring discredit upon the Society, shall be subject to expulsion by a vote of two-thirds of the members present at any general meeting." The proposition, although ably put by the mover, met with general disapproval. The possibilities of libel actions arising out of such a rule, if it were adopted, were discussed with an enthusiasm that would have done credit to an assembly of lawyers. We pass no opinion on this matter; we simply record the facts, as we hitherto have done; but we do fail to see what honourable men have to fear, other than its then acknowledged necessity, even were such a resolution adopted. Mr. Jukes, in strongly opposing the motion, admitted that opinions differed, so much so, that "what one man would consider irregularity of conduct another man would think perfectly fair." That is so, it is the way of the world; and as other men, so are lawyers—they differ in their opinions. It is just possible that the adoption of a resolution as that referred to would not place the Society or the officials in such an awkward

position as is supposed; but, on the other hand, it is probable that a step of this kind would meet with the general approval of the country members. Mr. Addison, however, withdrew his motion, and Mr. W. H. Fowler suggested that he would bring forward a substitute proposition, to be worded by himself, the Secretary, and Chairman of Committee at some future time. This will be to the effect that members in arrear shall be struck off the list, making no provision for the expulsion or removal of members otherwise. There is now, perhaps, no necessity for the severer clause, as the lessons of the past will serve as excellent warnings for the future. Meanwhile, the matter rests *sub judice*, and, notwithstanding the small balance and large indiscretions, the National Chrysanthemum Society starts hopefully on what promises to be a successful year. We have no other wish than to strengthen the Society, and our desire is to see it enjoy the confidence of the whole Chrysanthemum community.

### THE PROPOSED INTERNATIONAL FRUIT SHOW.

It will be remembered that several meetings were held last year, under the presidency of Sir James Whitehead, Bart., M.P., with the object of organising a great Exhibition of fruit in London. It was proposed to hold this Show on a site near the Thames Embankment, and Her Majesty the Queen honoured the project with Royal Patronage.

After a few meetings were held in furtherance of the movement, and the terms of the schedule arranged, political turmoil ensued and diverted the attention of the nation. It was, in consequence, decided to defer the consideration of the subject till early in the present year.

At the first meeting that was held it was evident that the obstacles to erecting a building on the Thames Embankment were too formidable to be overlooked, and on the proposition of Mr. T. F. Rivers an endeavour was made to arrange with the authorities at South Kensington through Sir Somers Vine, Secretary, for holding the Show in the Imperial Institute, which is to be opened in May. The project was placed before Sir Somers Vine by Mr. Richard Dean, Secretary to the Fruit Exhibition Committee, and appears to have been long under consideration, for it was not until Monday last that the reply from the Imperial Institute could be placed before a meeting at Anderton's Hotel. Sir James Whitehead not arriving in time to take the chair, H. R. Williams, Esq., presided, and there were present Messrs. T. B. Haywood, Philip Crowley, J. Laing, G. Gordon, and J. Wright. After the correspondence was read, in which Sir Somers Vine announced the inability of the Commissioners to give a definite reply (with the view to arranging for the Show) till after the opening of the Imperial Institute in May, it was thought the time would then be quite inadequate to complete the necessary arrangements, even if the reply were favourable. Mr. J. Wright thereupon moved, on the grounds indicated, "That it is inadvisable to proceed with the Exhibition this year." This was seconded by Mr. T. B. Haywood and carried unanimously. Sir James Whitehead, who arrived immediately after the business was over, at once concurred in the prudence of the decision.

It may be presumed that the plethora of shows announced to be held in London this year, was an element not without effect in influencing the Committee in the spontaneity of their action; but be this as it may, the proposed Exhibition lapses at present and the project will no doubt be considered again at some future favourable opportunity.

### HARDY FLOWER NOTES.

WITH February the outdoor garden begins to acquire a fresh interest. With these longer and brighter days the memory of black frosts and their paralysing effect on vegetation begins to sink into oblivion. Not that they are absolutely forgotten, for here and there some luckless plants show tokens, all too evident, of the fierce ordeal they have undergone. Here and there, too, we see plants which, in ordinary seasons, are much further advanced, but this year have failed to keep their wonted time. Wonderful is it, however, to see the rapid progress which some of these are making now that mild weather has come to urge their growth.

First, of course, for notice are the Snowdrops—these "Fair Maids of February," which we have so eagerly longed for through the long frost. True, the Corfu Snowdrop, *Galanthus corcyrensis*,

under the shelter of a bellglass, has been with us since the end of November, but it hung its head and drooped to the ground as if in supplication that more genial weather might attend her flowering time. Now, however, its congeners of many kinds are rushing into flower with eager haste, and had I not so recently written at length of this flower, many would call for special note. But a brief mention can be made, however, although as I write they are before me in various forms and sizes, from a single flower of some of the rarer kinds to the common *G. nivalis*, showing their white blossoms at the base of a hedge, on the rockeries, or in the borders. Contrary to expectation this species came into flower only some two or three days later than last year, but its simple beauty is eclipsed by the large and fine *G. Imperati Atkinsi*, with its long blooms and taller stems, and by some of the best forms of the Bithynian *Galanthus*, or by the exquisitely formed flowers of some of the better varieties of *G. Fosteri*, now in bloom, from imported bulbs. But, as Lord Tennyson in "The Last Tournament" makes the "swarthy one" say:—

"The Snowdrop only flowering thro' the year,  
Would make the world as blank as winter-tide."

So other flowers claim our notice even at this early season.

There, on the slope at the base of a tree sheltered by a wall from the rude north wind, Miss Jekyll's Primrose Munstead Early White has been in flower well nigh all the last three months, and its pretty flowers have brightened an otherwise dull corner. Not that these flowers are of the highest order of merit from a florist's point of view. They are "pin-eyed," and neither of the best form nor of the largest size. There are few Primroses, however, which have so prolonged a season of flower, or which in spring so cover themselves with blossoms. This is what some growers who have not grasped the merits of the flower fail to understand. Munstead Early White was introduced as a "bedder" and as a winter bloomer, and by its fulfilment of these qualities must stand or fall. It is, with me, admirably adapted for these purposes.

On the rockery, with only the protection of a sheet of glass but open to the frost and wind, the delightfully pretty *Saxifraga luteo-purpurea* forms a dense mass of rigid foliage, which is ever attractive, and now is especially so when spangled with the pale but bright yellow buds now just opening. It grows readily on a rockery facing the south-west in a pocket filled with sandy peat and gritty gravel from the seashore containing a liberal proportion of broken shells. This gravel is also used for surfacing the soil for this *Saxifraga* and many other plants. It does not seem to be very generally known that the name of *S. Frederici Augusti*, under which appellation this plant was first introduced, is a distinct plant, and as yet rare in cultivation.

In another part of the rock garden *S. Burseriana major*, long delayed by the frost, is now bristling with buds, many of which are showing colour and will soon be in full flower. The whole appearance of these spring tufts, with their buds crimson when closed but crimson and white when half open, is very pleasing.

Near by are many flowers of the charming little *Cyclamen coum* from imported bulbs, which are this year earlier in bloom than established corms. Whether for the rockery, alpine house, or cold frame, this little plant, with its kidney-shaped leaves and crimson-purple flowers, forms one of the most pleasing objects of the garden. It is wonderful to see its recovery after the hard frost, when the leaves seemed to hang limp and lifeless and as if nothing could restore them to their natural beauty. Yet now these same leaves are bright and healthy looking again, and apparently none the worse for their season of trial.

One cannot pass on either without a word of praise for the white Heath, *Erica carnea alba*, which has since November been a picture of beauty on the top of a rockery, where it has full exposure. It has stood unscathed, and is now in full beauty, with its bright green foliage and its neat white flowers more plentifully produced than usual. In another part of the garden the type *E. carnea* is covered with its flowers, which are now assuming the pink colour which, with their wax-like texture, makes them so bright and attractive.

Another flower which came into bloom in the open in January, but which, through my carelessness in not protecting it with a zinc ring fell a victim to the raids of the slugs, which seem to find in it a toothsome morsel, is *Colchicum crociflorum*, which has pretty little white flowers lined with purple on the outside. Fortunately, however, the foliage does not seem so attractive, and another year one may hope to have better success. This *Colchicum* seems to increase very slowly. I have had mine for some seven years or so, and have as yet had no offsets.

The late character of the end of 1892 has much affected the flowering of the later Meadow Saffrons, and when the frost came *Colchicum pannonicum* and *C. latifolium* were still in flower. A sheet of glass on wire supports was placed over these, and the

flowers were by this simple means preserved, and now (February 3rd) are bright and fresh. Another one, *C. Decaisnei*, which in 1891 flowered in December, is now only piercing the soil preparatory to blooming. The yellow spring Meadow Saffron, *C. luteum*, has not yet appeared, but I hope to see its yellow flowers ere long.

The earlier *Croci* are unusually late, and *C. Imperati*, usually one of the earliest and best, is coming on but slowly, and to all appearance will not be long in advance of some of the others. Meanwhile *C. vitellinus* is the prettiest in flower outside where its yellow blossoms are much appreciated. A clump of *C. longiflorus* protected by a handlight, and one of *C. Thomassi* are still in flower. It is a pity that our winters are so stormy and so uncertain that we cannot enjoy these pretty flowers to the full in the garden.

Many of these *Crocus* species are, however, worthy occupants of a cool greenhouse or of the alpine house, and in my cool greenhouse *C. bannaticus* and *C. Korolkowi* have opened their blossoms in advance of those of the same species grown in the open garden. Very beautiful is the former, and the latter, of a curious dusky or tawny brown outside and yellow inside, forms a fitting companion for the fine, deep purple flowers of *C. bannaticus*.

The garden has now much of beauty in the way of foliage. Tufts of mossy verdure are shown by the Mossy Saxifrages and little mounds of silvery hue by the encrusted forms, besides the varied colours and tints of the flowering sisterhood now seeking to show that soon the glad time of spring will reveal to us that flush of beauty which she yearly brings. Thus, though the garden cannot as yet vie with the greenhouse with its forced Tulips, Narcissi, and the many flowers which its sheltering roof and its genial heat bring to view, it is at least not barren of interest; not a flowerless waste, but a spot where many gems may be seen and many lessons of beauty learned.—S. ARNOTT.

### PROPAGATING BEDDING PLANTS.

ALTHOUGH many strains of *Lobelias* come fairly true in habit and colour, it is still preferable to propagate from cuttings if a sufficient stock can be obtained to start with. Brighton Blue is, I think, still the best dark variety we have, and is largely propagated in many gardens, but I find it a great advantage to have also a stock of plants bearing flowers of a much lighter shade. I made an excellent selection last year out of a number of seedlings, and we are now getting strong cuttings from old plants potted in the autumn. These are inserted an inch apart in shallow pans containing a layer of sharp sand, without drainage or soil. The pans are placed in a close warm pit with bottom heat, where they root rapidly, and are then transferred to boxes filled with rich light soil; in these the plants are placed 3 inches apart, are again transferred to a close pit till growth is well advanced, when they are hardened off, and form good sturdy plants by bedding-out time. It is not necessary to spend time in cutting to a joint or trimming in any way, as they emit roots readily enough at any point when inserted. With the command of good bottom heat care should be taken not to allow the sand to become dry at any time, or when water is given the cuttings will decay under the surface of the sand, consequently many are led to think they have "damped" off on account of being kept too moist, whereas it is in reality the great change from aridity to moisture which has brought it about.

Other excellent methods of propagating are to insert cuttings in well drained boxes containing a layer of soil 2 inches in depth. These boxes can be placed on shelves or over the hot-water pipes. In either case the essentials to success are the maintenance of a temperature not less than 60° and uniformly moist soil; the latter condition is best maintained by light but constant syringings. When only a limited number of cuttings can be obtained and it is desirable to increase the stock as fast as possible, a handlight should be placed over the hot-water pipes or a flue in some warm corner; if a bottom is then formed of boards and an inch of sharp sand placed on the top, an excellent propagating case is obtained, in which limited space large numbers of cuttings may be quickly rooted if each batch is transferred to boxes as soon as growth begins.

*Coleus* are not generally wanted in very large numbers. A sufficient stock may therefore be readily raised by inserting the cuttings in 6-inch pots, these being well adapted for standing on hot-water pipes around Cucumber and Melon houses, positions in which they root quickly and with certainty. Bottom heat is the principle essential to success. If no better position presents itself than a vinery in which the temperature falls below 60° the cuttings ought to be placed under handlights, glasses, or frames. In all instances the plants should be placed into 3-inch pots when well rooted; they will then, in a short time, supply other good cuttings.

If these are not wanted for insertion they should still be removed to induce sturdy and compact growth.

*Alternantheras* are usually required in large numbers on account of the great beauty of their varied markings. I have frequently noticed when about to commence the propagation of *Alternantheras* that the growth made during winter becomes hard and wiry, producing flowers freely up the stems, and many of these ultimately develop into seed pods. It is useless to insert such pieces as these, for they never make satisfactory progress. The best way to deal with plants in this condition is to shorten all growths to within an inch of their base, rub off any flowers which are left, and plunge the pots in bottom heat, good strong soft cuttings are then quickly produced. These root freely in almost any position where the temperature ranges from 60° to 80°. When their propagation is carried on in vineries in which the foliage on the Vines is in an advanced stage, it is important to keep the boxes near the front of the house, or on shelves; otherwise many cuttings will be lost through damp. If a bed having pipes to supply bottom heat can be devoted to propagation purposes, thousands of plants may be speedily raised. A few inches of cocoa-nut fibre refuse, placed in the bottom, form excellent material to stand the boxes upon, or to plunge pots containing other cuttings in. When preparing compost for *Alternanthera* cuttings I like it to consist of one-half leaf mould and a similar quantity of old potting soil. This mixture induces a quick and somewhat soft growth, exactly what we require when raising large numbers of this type of bedding plants.

*Mesembryanthemum variegatum* requires a compost containing plenty of sharp sand or other gritty matter, and comparatively little leaf mould to insure the production of firm growth, which is not so liable to decay at the base as that grown in richer soil. Given good cuttings to begin with there should be no difficulty in rooting *Mesembryanthemums* without the loss through damp, which often occurs. Instead of being shaded from sunshine the cuttings should be placed in the full glare of it on shelves or stages near the glass, in a stove temperature, taking care that the soil is kept uniformly moist. Under such conditions 90 per cent. of the cuttings will root.

*Iresines* should, if possible, be placed in a close frame where there is good bottom heat, otherwise their soft leaves shrivel much, and progress is greatly delayed. *Ageratums* will succeed admirably when given conditions similar to those recommended for *Alternantheras*. They will, however, endure more shade, as damp seldom affects them.

*Fuchsias*, *Heliotropes*, and *Dahlias* root well in a temperature ranging a few degrees lower than the plants previously named require. In each case the cuttings should be kept close; bottom heat is an advantage, but not a necessity. The showy plants last named should, if possible, be taken off with a heel, and be placed singly in pots.

An excellent method of rooting Tuberous *Begonias* is to place cuttings singly in thumb pots, using loam and leaf soil in equal parts as the compost, and plunging the pots in fibre refuse where there is a slight bottom heat and a top temperature of 60°. If the house or pit in which they are located is kept close and moderately moist no additional covering of glass is necessary. No shade is required except in very bright weather.

Every one of the above plants may be propagated freely on a hotbed made up in the open air with a frame placed upon it, but it is essential that the heat should be kept regular by the addition of linings. As soon as there are signs of its decline sawdust or fibre refuse ought to be placed upon the bed as a suitable medium for plunging in, and also to prevent the heat escaping rapidly. It is not wise to begin the propagation of such tender plants as *Alternantheras* and *Coleus* in a manure bed till the beginning of March, because in very severe weather much covering is necessary to prevent heat escaping. The cuttings in consequence become weak and drawn through want of light, and too wet through drip caused by condensed moisture.—D. W.

### SILVER MEDAL ESSAY.

#### MANURES AND THEIR USES.

By Mr. G. A. BISHOP, *The Gardens, Wightwick Manor, Wolverhampton.*

THE constant removal of crops from the ground, and fruit from the trees and bushes, causes the removal of certain constituents which, if not restored, would eventually make the garden unremunerative. Gardens and fields thus robbed of their plant food are said to be exhausted, and the addition of the constituents which have been removed is what we know as manuring. In some cases the land is naturally poor; it may be especially deficient in some particular constituent which may be given to it in the form of manure. The manure

applied may, and does, act upon the constituents of the soil, decomposing them and rendering them soluble, when they can be utilised by the plant. A highly important effect of manuring is that it alters the physical character of the soil. Farmyard manure owes its value to a great extent to its mechanical action in dividing and pulverising the soil. Stiff land always works easier after liming, and the addition of marl gives greater consistency to sandy soils. A gardener or farmer should know before cropping his ground the constituents that a particular crop requires for its support, and whether these constituents are present there in a soluble state; if they are not, he should ascertain the best way of placing them in the ground at the least cost and trouble. If he has a thorough knowledge of these points it will prevent his wasting money in the form of applying manure for crops that may be of no practical value to them, and which could otherwise be more profitably used in the right place and at the right time to be serviceable.

Manures are generally divided into two classes. First, natural; and secondly, chemical. By natural manures we mean, or understand, the excrement of animals and residues of crops. These form the natural manures of the farm; with them we should, I think, include guano and the blood, bones, and other remains of animals. These form what we know as general manures—*i.e.*, those which supply the main portion of the losses of the soil, and therefore provide those requirements of plant life that are appropriated by the roots of trees and crops.

#### NATURAL MANURES.

**FARMYARD MANURE.**—This contains the excrement of the horse, cattle, sheep, and pigs, with litter. The value depends upon the method of treatment upon the animals producing it, and their food. It is the most valuable from fat and full grown cattle fed upon corn and cake, as they remove less from the corn and cake than young and lean stock do, or than cows do in production of milk.

**NITROGENOUS GUANO.**—This has been formed from the excrement of and remains of the bodies of sea-fowl. When fresh it is highly nitrogenous, and consists mainly of uric acid and calcium phosphate. In hot, dry climates the substance rapidly loses moisture, and the nitrogenous matter is preserved. This nitrogenous guano comes from Peru, Chili, South Africa, and Patagonia. It varies in its constituent parts, and contains from 3.5 per cent. to 14 per cent. nitrogen, and 12 to 20 per cent. of phosphorus pentoxide. Some samples contain potassium as potash sulphate.

**PHOSPHATIC GUANO.**—In moist and rainy districts the nitrogen is rapidly converted into ammonia, which is lost by evaporation and drainage, a phosphatic guano remaining. Phosphatic guanos have been, and are obtained from a great variety of sources, Bolivia, Australia, and the islands of the Pacific Ocean, especially contributing. They contain 30 to 36 per cent. of phosphorus pentoxide, and about 1 per cent. of nitrogen.

**BONES.**—Seldom used in the fresh state; they are usually steamed or boiled to extract the fat. They contain about the following percentage of nitrogen and phosphorus pentoxide.

	NITROGEN.		PHOSPHORUS PENTOXIDE.	
Fresh bones ..	3 to 4	per cent.	19	per cent.
Steamed ..	3	" 4	23	"
Boiled ..	1	" 5	25	"

Bones are applied to the land as kibbled about half inch fragments, as bone meal or flour, and as bone dust. They are also used in the production of superphosphates.

**DRIED BLOOD.**—A very valuable manure if used in a properly dried state. It contains much nitrogen which is readily available for the use of crops. The commercial article should contain 10 per cent. of nitrogen.

**MEAT MEAL OR MEAT GUANO.**—The residue from the manufacture of meat extract in South America, New Zealand, and Australia is so named. The composition depends upon the proportion of bones ground up with it. It contains from 6 to 13 per cent. of nitrogen and 1 to 17 per cent. of phosphorus pentoxide.

**HOOF AND HORN.**—These, with the residue after manufacture of combs and buttons, are ground up and form a valuable nitrogenous manure containing about 15 per cent. of nitrogen.

**SOOT.**—This is used as a top-dressing for corn and garden crops. It is very valuable when mixed with potting compost, and also with other manures in liquid form for watering various soft and hard-wooded plants. It yields about 5 per cent. of nitrogen.

**FISH MANURE.**—This is used when certain crops or plants that

require phosphorus and ammonia. Valuable for Vines, Peaches, and most stone fruit, and largely used for Chrysanthemums. Fresh sprats contain 63 per cent. of water, 2 per cent. of nitrogen, 21 per cent. of ash, which contains 43 per cent. of potash and 9 per cent. of phosphorus pentoxide. Fish offal is simply dried and powdered; it contains about 8 per cent. of nitrogen and 6 to 13 per cent. of phosphorus pentoxide.

#### CHEMICAL MANURES.

These include the great number of substances, most of which are rich in one, two, or most of the constituents necessary to be present in the soil; such as nitrogen, potash, phosphorus, and other elements or compounds.

**SODIUM NITRATE** occurs naturally in large beds in Chili and Peru, and is known as Chili saltpetre. This is one of the most important sources of nitrogen, probably the most important. The impure deposit called caliche contains about 50 per cent. of pure nitrate, and is purified by boiling with water; the liquid is allowed to stand till the solid impurities have settled, and is then run off into tanks, and the pure nitrate crystallises out from the solution. The commercial salt should contain 95 per cent. of real nitrate, and 15.65 per cent. nitrogen. This nitrogen is present in the form most readily assimilated by plants, and its great solubility renders it the most powerful and rapid of all nitrogenous manures.

**SALTPETRE OR NITRE** forms an efflorescence on the soil in hot climates, as in India. This efflorescence is collected and treated with water, in which the nitrate of potash dissolves. On allowing the liquid to stand the earthy and clayey matter subsides, the clear liquid is drained off and evaporated, when crude nitrate of potash remains.

**POTASH SALTS (KAINIT).**—Crude potassium salts are generally used under the name of kainit, which is found as a deposit at Stassfurt in Prussia. A good sample should comprise the following ingredients:—

#### COMPOSITION OF KAINIT.

Water ..	3.36
Combined water ..	10.88
Sulphate of potash ..	24.43
Sulphate of calcium (gypsum) ..	2.72
Sulphate of magnesium ..	13.22
Chloride of magnesium ..	14.33
Chloride of sodium (salt) ..	30.35
Insoluble matter ..	0.71

For the benefit of readers not acquainted with the reading of chemical analysis, it will be clearer if I say when 100 lbs. of kainit is applied to a Potato or Carrot crop 24.43 lbs. of the 100 will be sulphate of potash, 2.72 lbs. sulphate of calcium, 30.35 lbs. chloride of sodium (common salt), and so on as is given in the analysis. Combined water is the water of crystallisation.

**POTASSIUM SULPHATE** ( $K_2SO_4$ ) is a compound where 2 atoms of potassium have displaced 2 atoms of hydrogen from sulphuric acid ( $H_2SO_4$ ).

**CALCIUM SULPHATE** ( $CaSO_4$ ) is also a compound, which occurs in nature, and is known as anhydrite, but a more usual variety of the sulphate is that termed gypsum. As will be seen, 1 atom of calcium displaces 2 atoms of hydrogen from sulphuric acid ( $H_2SO_4$ ).

**MAGNESIUM SULPHATE** ( $MgSO_4$ ).—This salt is found in nature combined with seven molecules of water, and is known as Epsom salts, soluble in water. A form combined with one molecule of water, known as kieserite, is very insoluble. Magnesium also displaces 2 atoms of hydrogen from sulphuric acid.

**MAGNESIUM CHLORIDE** ( $MgCl_2$ ) is a compound of magnesium and chlorine, it occurs in the "bittern," or mother liquor remaining in the purification of common salt, chloride of sodium.

**SODIUM CHLORIDE** (NaCl) is a compound of sodium and chlorine, and occurs plentifully in nature as rock salt, also in sea water. Sodium chloride is found in rivers, and small quantities in the air in all parts of the globe. Though these various compounds can be produced in the way I have shown (with a view of instructing the uninitiated) they also occur in nature by themselves or combined.

**AMMONIUM SULPHATE.**—This is procured mainly from gas liquor, an alkaline liquid, which is obtained as a by product in the purification of coal gas. This contains 4 to 40 lbs. of ammonia per 100 gallons; some little is also obtained from bone liquor. The liquid in either case is distilled (usually with lime), and the ammonia given off passed into saturators containing sulphuric acid; after a time ammonium sulphate crystallises out, and is collected with perforated ladles. In some cases the gas liquor is directly neutralised with sulphuric acid. The sulphate of ammonium so made is likely to contain ammonium sulpho-cyanide, which is very objectionable, being poisonous to plants. This may be detected by dissolving some of the ammonium sulphate in water, and adding to it a few spots of solution of perchloride of iron (obtainable from any chemist), a blood-red colouration is produced if ammonium sulpho-cyanide is present. Commercial ammonium sulphate is usually guaranteed to contain 24 per cent. of ammonia, which is equal to 93.18 of ammonium sulphate.

**BONE ASH.**—This is the residue, obtained when bones are completely burnt. The commercial article is mostly imported from South America, and usually contains 70 per cent. of calcium phosphate. The calcium phosphate of animal matter is more readily attacked by the solvents of the soil than the same compounds occurring in mineral phosphates.

**BASIC SLAG OR PHOSPHORIC SLAG.**—When steel is made by what is known as the "basic Bessemer process," the whole of the phosphorus in the pig iron used, sometimes 3 or 4 per cent., combines with the lime also used in the process, and goes into the slag, which contains about 50 per cent. of lime and an average of 17 per cent. of phosphorus pentoxide. This slag is ground into very fine powder, and passed through a sieve of 100 meshes to the inch linear. This is important. The oxide of iron, which is also present, is not found injurious to plants, as was at first expected. In 1887 over 500,000 tons of this slag was made in Europe, and nearly the whole was used as a manure. It is estimated that the phosphorus pentoxide in finely ground slag has half the manurial value of the same constituents in superphosphate.

#### ANALYSIS OF BASIC SLAG.

Lime .. .. .	50.0 per cent.
Magnesia .. .. .	4.0 "
Alumina .. .. .	2.0 "
Silica .. .. .	8.0 "
Iron oxide .. .. .	14.0 "
Manganese oxide .. .. .	5.0 "
Phosphorus pentoxide .. .. .	17.0 "

**SUPERPHOSPHATES.**—The naturally occurring phosphates of calcium, such as apatite, sombreroite, and coprolite, cannot be profitably used as a manure in the raw state, as they are very insoluble in water. By the action of sulphuric acid the greater part of these insoluble phosphates may be converted into an easily soluble form known commonly as superphosphates. Owing to its great solubility this forms the most satisfactory method of adding phosphorus to the soil. The effect is more marked when required for the needs of a particular crop rather than for the permanent improvement of the soil. Bones, bone ash, and animal charcoal are also converted into superphosphates in a similar manner. The following is an analysis of a superphosphate made from coprolites. The composition of superphosphates varies very much.

#### MINERAL SUPERPHOSPHATE.

Calcium superphosphate (soluble) .. .. .	19.47
Tri-calcium phosphate (insoluble) .. .. .	7.59
Calcium sulphate (gypsum) .. .. .	37.47
Water .. .. .	27.93
Silica .. .. .	4.07
Alkalis, iron oxide, &c. .. .. .	3.47

**PRECIPITATED PHOSPHATE.**—Certain phosphatic minerals are unfit for conversion into superphosphates. This may be due to the presence of objectionable constituents, such as ferric oxide, or alumina, or to the small quantity of phosphates contained in them. These minerals are treated with acid (sometimes after calcination), and the phosphates dissolved out; this is then precipitated with lime, chalk, or calcium sulphhydrate. The phosphate so precipitated stands next in value to superphosphate, inasmuch as some samples contain up to 40 per cent. phosphorous pentoxide. It is a very concentrated manure, and is much used on the Continent.

**CALCIUM COMPOUNDS.**—These are used under the form of chalk, lime, gypsum, and marl. They are especially useful on heavy land, upon land deficient in lime, peaty soils, and on those containing much vegetable matter.

(To be continued.)

#### NATIONAL ROSE SOCIETY.—"THE ROSE DERBY."

SURELY "a comedy of errors"—no better title could be given to the recent blunders committed by those responsible for the tactics and generalship of the "late land division" of our Rose army. Once after another these leaders have fallen into the very traps which they fondly imagined they had so carefully laid for the discomfiture of the southern army.

First and foremost came the Rev. J. H. Pemberton "beating the air" with an attack on me, and here I may say I completely and unreservedly accept his explanation, even with its conditional "IF" in capital letters. Then came "J. B." (page 109) with a fable about Messrs. Hall and Whitwell, which "D., Deal," (page 131) has demolished in his own inimitable and convincing way; but the climax, and cream of the whole joke, I think, is in the fact that in your issue of this week "W. R. Raillem" (page 131) has fallen on and slaughtered one of his own party. Poor "J. B.!" he must feel quite demolished, smitten hip and thigh on the same day, not only by the ephemeral southerner, but also by the more hardy northerner—even his own familiar friend. "Et tu, Brute!" However, to finish with another quotation from Shakespeare, let us still hope that "all's well that ends well."—CHARLES J. GRAHAME, *Croydon*.

#### N.R.S. FIXTURES.

I AM glad to see the note from "D., Deal," (page 131) re the retirement of Messrs. Hall and Whitwell, but can assure your correspondent that the reason I mentioned is the one constantly assigned at the time by members of the National Rose Society. When such able practitioners suddenly cease their efforts a certain amount of curiosity is naturally felt as to the cause, and all of whom I inquired about it gave the reason I stated, and as it seemed a very likely one I supposed it was correct. I am sorry now to learn that it was rather lack of "staying powers."

#### TEAS IN MIXED CLASSES.

My whilom opponent, "W. R. Raillem" (page 131) rather misses the point of my complaint. I do not mean that there were any "especial favour" shown to the particular blooms of Teas exhibited, though I do know very excellent judges who hold that Teas *per se* are always more deserving of honour than H.P.'s, but that boxes of Teas exclusively being allowed to compete in the mixed classes constitutes an "especial favour" to Teas, which is not enjoyed by H.P.'s. One portion of the schedule is headed "Tea and Noisette Division," and it surely does not need any argument to prove that *that* is the place for boxes of these varieties only. If this division did not exist I should consider it "especial favour" if H.P.'s alone were allowed to win, but with the ample provision thus made for Teas only I still think that such boxes should not be allowed in the so-called mixed classes. In the case of H.P.'s cited by "W. R. Raillem" it was quite natural that the "Tea men" should not complain, because they had the entire division to themselves in which not a solitary H.P. might appear.

My reply to your correspondent's last question is that at present I should not like a rule that there must be some Teas in the mixed boxes, but I should like to see one class in each of the sub-divisions A to F for H.P.'s only (of course I know of the classes for 12, 9, and 6 of one H.P.) and then I would insist that stands in the mixed classes should contain both Teas and H.P.'s. I hope to see some such arrangement in the schedule for 1894.—J. B.

#### DISCUSSION ON POTATOES.

##### THE BRUCE.

IT is very evident that Potatoes, like Apples, are not suitable for all soils; by this I mean varieties growing on heavy land in one place appear totally unsuited for similar soil in another district. I see, on page 116, Mr. E. Molyneux says the Potato under notice does not produce tubers of first-rate quality in his district. Now, my experience teaches me that The Bruce is one of the best varieties we have in the market. I quite agree with Mr. Molyneux, that it is a form of Magnum Bonum. Mr. Findlay of Markinch, the raiser, says it is the result of a cross between Paterson's Victoria and Late Rose, so it will be seen by its parentage that the quality comes from the former variety. It is a heavier cropper than Magnum Bonum, and the flavour is far superior to that variety. On my heavy soil the tubers turn out well, and when cooked they are like balls of flour. The market growers on the north side of London have almost discarded Magnum Bonum in favour of The

Bruce. As a disease resister it stands unique. Every grower who has bad Potato soil should give this variety a trial.—J. B. RIDING.

#### LADY TRUSCOTT.

UNTIL reading the article (page 105) by Mr. Fenn, I was not aware that the above Potato was one of his raising. I have said much in favour of Ringleader, another of his raising, and I cannot, or ought not, to say less of Lady Truscott. With me good white round Potatoes of the best cooking quality are not over-plentiful, but Lady Truscott is simply grand, coming in after the second early. It might, I suppose, be called a midseason variety. I have grown it for some years, and hope to do so many more yet. Quite recently I sent for a change of seed, which is quite the best thing to do where the soil is not of the best for Potatoes. The tubers are not large, but when cooked are particularly white, and of excellent flavour.—E. M.

#### PLANTING LATE POTATOES.

I DO not think the advice given by "O. C." (page 116) as to the late planting of main crops, will be universally accepted as being the best. Many persons put these in first, finishing with the medium kinds; but as "O. C." does not tell us what he calls "late," it is hard to say when they should be planted in his opinion. I have seen many acres of Potatoes spoilt through not planting the tubers early enough. When the planting of such sorts as Magnum Bonum, for instance, is left until the second week in May what chance is there for the haulm to develop? The middle of April is a much better period to plant field Potatoes, especially where the soil is heavy. There need be little fear of blanks if the sets are properly chosen.—S.

#### STORING POTATO SETS.

As "O. C." (page 116) rightly points out, much of the success or otherwise of the Potato crop emanates from the manner in which the sets are stored. In many gardens these cool structures are not available where a number of seed tubers can be stored. My plan is to dig the Potatoes on a fine day, and allow them to lay two or three hours in the sun before storing. We place them in heaps in the Mushroom house for a month or so until that structure if required for its legitimate use. The Potatoes are then pitted, a layer of straw separating one sort from another. Once during the winter the tubers are turned over, choosing a dry day, which dissipates any moisture that may have collected about the sets. Any growths that have formed are removed. By the end of February the Potatoes are ready for removal to the "sprouting" place, some of the early sorts having been taken out in January. The shelves in the fruit room are utilised for "setting up" the Potatoes, choosing a position as near to the window as possible, so as to afford both light and air as a means of inducing the growth to be sturdy. I like to have the sets with shoots half an inch long at planting time.—M. P.

#### CANKER IN FRUIT TREES.

(Concluded from page 132.)

IT will be seen from the following table the importance of applying manures to benefit fruit in the first stages of swelling is paramount, as a large proportion of the mineral matter contained in the Apple is stored up during the early part of its growth:—

#### "ANALYSIS OF BEN DAVIS APPLES IN THREE STAGES OF GROWTH. ACTUAL QUANTITIES AND PROPORTIONS PER CENT.

	Unripe Apples. July 9th.	Ripe Apples. October 23rd.	Small Apples. October 23rd.
Average weight of whole fruit ..	47.70	215.00	70.40
Weight of flesh in fruit ..	—	201.00	67.70
Weight of core in fruit ..	—	14.00	8.70
Weight of ash in fruit ..	5.51	4.03	4.81
	Per cent.	Per cent.	Per cent.
Amount of flesh in fruit ..	—	93.40	87.60
Amount of core in fruit ..	—	6.60	12.40
Ash in whole Apples ..	0.29	0.27	0.31
Carbon in same ..	2.35	6.04	0.52

The following table, taken from the same source as the preceding, namely—"Bulletin of the Missouri (Columbia) Department of Horticulture," shows an equal weight of small inferior fruit extracts more substances from the soil than does the large, and still further points to the importance of supplying soluble manures and early, so as to get the most value out of them—secure it in the fruit.

#### "MINERAL CONSTITUENTS OF BEN DAVIS APPLES IN THREE DIFFERENT STAGES OF GROWTH.

Per-centage quantities and actual quantities in 10 bushels of fruit.

	Unripe Apples. July 9th.	Ripe Apples. Oct. 23rd.	Small Apples. Oct. 23rd.
	per cent. oz.	per cent. oz.	per cent. oz.
Silica ..	0.58 0.13	1.23 0.26	2.16 0.59
Ferric oxide ..	0.47 0.11	0.46 0.11	0.66 0.18
Phosphoric acid ..	8.96 2.07	8.20 2.23	8.73 2.39
Lime ..	6.85 1.53	5.66 1.21	8.85 2.42
Magnesia ..	4.80 1.11	4.30 0.92	4.76 1.30
Potash ..	54.02 12.49	56.74 12.12	52.44 14.35
Soda ..	2.10 0.49	1.94 0.41	2.03 0.57
Undetermined ..	22.22 5.14	21.47 4.50	20.62 5.56
Total ..	100.00 23.12	100.00 27.76	100.00 27.36

If 10 bushels of fruit is the full produce of an Apple tree at its best, and there being seventy-five trees per acre, at 24 feet apart, No. 1 sample has abstracted by July 9th 10 lbs. of phosphoric acid, 7¼ lbs. of lime, and 52¼ lbs. of potash. No. 2, ripe Apples, 10¼ lbs. of phosphoric acid, 5½ lbs. of lime, and 56¾ lbs. of potash; and No. 3, small Apples, 11 lbs. of phosphoric acid, 11¼ lbs. of lime, and 67¼ lbs. of potash. The worthless trash (small Apples) abstract more phosphoric acid by three-quarters of a pound, 5¾ lbs. more lime, and 10½ lbs. more of potash than the same quantity per acre of full grown, marketable fruit. That is another reason why the produce of neglected orchards present such a deplorable figure beside imported fruit in the markets—namely, waste the resources of the soil on a worse than useless crop. The fact is, the culture of 99 per cent. of the orchards in this country has for its sole object soil exhaustion, for very few get anything returned to the soil. Yet the clamour is for protection—make consumers buy rubbish. Never!

The following analyses by Herr F. F. Schutt show the importance of an early supply of food elements. The analyses are given in "Biedermann's Centralblatt," 1892, and in the *Gardeners' Chronicle* show the components of Apple tree leaves on the dates given in the table.

	May 25th.	Sep. 20th.
	Per cent.	Per cent.
Constituents:—		
Water ..	73.36	60.71
Ash ..	2.33	3.46
Nitrogen ..	2.94	2.48
Composition of the Ash:—		
Phosphoric oxide ..	10.47	5.82
Potash ..	10.82	11.63
Lime ..	17.40	27.91
Magnesia ..	9.77	4.81
Iron oxide ..	1.49	1.41
Silica ..	1.07	1.14

The only ingredients worth noting are the phosphoric acid, potash, lime, and magnesia, except the nitrogen. All the analyses tend to confirm M. Ville's statement that only nitrogen, potash, lime, and phosphoric need be added to any soil in the manure. It appears, however, from the above analysis that magnesia is an important element in Apple tree leaves, and points to the necessity of supplying it to Apple orchards, therefore the value of kainit as a manure in supplying that element, and soda as well as potash. A deficiency of magnesia may in some soils have something to do with the tendency of Apple and Pear tree leaves, shoots, and fruits to attacks of scab fungus (*Cladosporium dendriticum*). But scab in Apples and cracking in Pears is worst in heavy soils where there is the largest per-centages of magnesia, therefore the evidence is in favour of the fungus being the cause, and nothing but the fungus.

Analysis of the wood and whole fruit of the Apple are given below.

	Wood.	Fruit.
Potash ..	19.24	35.68
Soda ..	0.45	26.09
Magnesia ..	7.46	8.75
Lime ..	63.60	4.08
Iron ..	0.07	1.40
Phosphoric acid ..	4.90	13.59
Sulphuric acid ..	3.29	6.09
Silicic acid ..	2.06	4.32

Nothing in these analyses show cause for deviation from the acknowledged principle of manuring fruit trees. However opinion may trend to the total replacement of natural by artificial manure in agriculture, it can never apply exclusively to fruit culture, for in the former there is always a large proportion of residues in roots and other parts of the crops in the soil; consequently there is no impoverishment by the use of chemical manures, but an actual increase of organic matter. In fruit growing there is no crop residue, except in orchards in grass, or in others in the shape of weeds; therefore those that recommend the complete discarding of stable or farmyard manure, and reliance solely on artificial, make a mistake. Nevertheless, a judicious displacement of natural manure by artificial has proved advantageous to the crops and a saving to the cultivator.

Bone superphosphate, by supplying phosphoric acid and lime in a soluble form, heads the list of suitable manures for fruit trees. Thomas' phosphate, or basic slag, also contains phosphoric acid largely (18 per cent.), and lime in a sufficiently soluble form where there is organic matter, as in gardens generally and new ground being prepared for planting with young trees, also for orchards in grass.

Potash can only be supplied economically in kainit, and no soil needs a supply except those deficient, the light and exhausted. Nitrate of potash is far too dear for general use, and the artificials employed in gardens often cost more than the crops are worth; but those that will have superlative products must not begrudge the extra means.

Nitrogenous manures come next in M. Ville's recommendation, and complete the list of what he considers necessary to apply to soils for the economic production of fruit. Sulphate of ammonia may suit good loams and heavy soils, but nitrate of soda is better for calcareous and light soils, if not for all, under judicious management, while none are so disastrous to the hardness of the trees where it is used injudiciously. It must always be applied to fruit trees during their growth and in the first half of the fruit swelling. Applied to trees already making enough wood it does no good, but harm; and supplied after July it only tends to a late growth, which being soft and the winter severe is often crippled—many trees for life.—G. ABBEY.

## MAXILLARIA PORPHYROSTELE.

THOUGH inferior to *M. grandiflora* and *M. venusta* the above species is by no means unattractive. It is a free-growing plant, resembling *M. picta* in general appearance; but the flowers are smaller, and lack the purple and chocolate spots on the petals and sepals. The pseudo-bulbs are orbicular-ovoid, and bear each a pair of dark green leaves about 5 to 7 inches in length and half an inch broad. The flowers are produced in profusion in early spring; they are about 1½ inch broad, of a uniform greenish-yellow colour with a purple column and streaks of the same colour on the lip and at the base of the petals. It is a native of Brazil, from whence it was introduced by Mr. Bull of Chelsea about 1873. It is figured in the "Botanical Magazine," t. 6477. A large plant is now flowering at Kew.

## SOBRALIA SESSILIS.

Plant of this uncommon, but exceedingly pretty *Sobralia* are now flowering at Kew. Though it is an old species, having been introduced from British Guiana by Schomburgk about 1840, it is still but rarely met with. This is no doubt due in a large measure to the short duration of the individual flowers, a circumstance which unfortunately militates strongly against the popularity of all *Sobralias*. It is a comparatively dwarf species, the stems being only about 2 feet in height. The flowers are produced from the top of the stem singly, but in quick succession. Unlike the well known *S. macrantha*, the stems of *S. sessilis* continue to grow and flower for several years. The flowers, though not so large as those of *S. macrantha*, are no whit less beautiful. The sepals and petals are white slightly tinged with rose; the funnel-shaped lip is rosy-pink with a faint touch of yellow. It is a free-flowering species, and possesses the further merit of blooming during the winter months.

## CÆLOGYNE FLACCIDA.

The specific name of this *Cœlogyne* refers to the drooping character of the inflorescence. The racemes are many-flowered and of considerable length, the flowers being set rather widely apart. The flowers are white, except the lip, which has the yellow blotch common to most *Cœlogyne*s. The pseudo-bulbs are 4 to 5 inches in length, the dark green lanceolate leaves which are produced in pairs are from 8 to 10 inches long. The plant has an erect habit of growth, and when in flower is very attractive. The flowers are produced very freely in winter and early spring, and last a long time in full beauty. *C. flaccida* requires an intermediate temperature—the *Cattleya* house suits it very well—and should be well rested. It was introduced from Nepal by Dr. Wallich, and first flowered at Wentworth in 1833. A plant is now in flower in the warm Orchid house at Kew.

## CÆLOGYNE ODORATISSIMA.

This graceful little Orchid was introduced to cultivation about the year 1863, and first flowered in this country in the Kew collection. It is a native of the Nilgiri Hills, where it is found growing on the trunks and branches of trees, or among stones and wet moss on the northern side of the hills. It is also found in Ceylon. It is a very dwarf species, the pseudo-bulbs being only about 1 inch high. The leaves are about 4 inches in length, and of a light green colour. The raceme, which is produced from the top of the pseudo-bulb between the young leaves, is slender and drooping, and bears about three flowers. The latter are pure white, except for a blotch of yellow on the lip, and are very sweetly scented. It is figured in the "Botanical Magazine," t. 5462.—A. B.

## PHALÆNOPSIS × INTERMEDIA, VAR. VESTA.

IN the hybridisation of Orchids the unexpected frequently happens, and, says "The Orchid Review," especially has it been so in the present case. The beautiful *Phalænopsis* × *intermedia* was long suspected to be a natural hybrid between *P. Aphrodite* and *P. rosea*, and this was at length proved by Mr. Seden by

artificial crossing. He afterwards fertilised *P. rosea* var. *leucaspis* with the pollen of *P. Aphrodite*, and the result is quite a distinct form of *P. intermedia*. *P. rosea leucaspis* differs from the type in having smaller flowers with shorter and broader segments, and the petals darker in colour than the sepals, and these characters are impressed on the hybrid, which differs from *P. intermedia* in much the same way. The flowers are smaller, the petals more distinctly rhomboidal, and the two teeth at the apex of the lip are straight, not curved inwards. The whole flower is of a lovely rose-purple, and as regards colour exceptionally distinct. This new acquisition was exhibited by Messrs. James Veitch & Sons at the meeting of the Royal Horticultural Society on January 17th last.

## SELENIPEDIUM × PHÆDRA.

This is a new hybrid, raised by Messrs. James Veitch & Sons of Chelsea, and the first to flower, in which the stately *S. Lindleyanum* of Mount Roraima is connected by hybridisation with its congeners of the Andean Cordilleras. *S. × Sedeni candidulum* was the seed parent, and therefore three distinct species are concerned in the parentage and the resulting progeny is one of the handsomest hybrids in the genus. The leaves are nearly as broad as in *S. Lindleyanum* and shorter than in *S. × Sedeni*, and the flowers larger than in either parent. Dorsal sepal 1½ inch long, oblong, obtuse, undulated at the margin, cream white, mottled with light rose to two-thirds of its length; lower sepal very broad, nearly sub-orbicular, concave, yellowish white; petals broadly linear, deflexed and undulated, about 3 inches long, light rose-pink with a white median line; lip helmet-shaped, bright rose-pink, the unfolded lobes yellowish white with a few crimson dots. Staminate yellowish white, fringed with crimson hairs at the back. It

FIG. 27.—CYMBIDIUM GRANDIFLORUM.

is a decided acquisition. It was awarded a first-class certificate by the Royal Horticultural Society on January 17th last.—(*The Orchid Review*.)

## CYMBIDIUM GRANDIFLORUM.

WHEN exhibited at the Drill Hall on February 14th by Messrs. F. Ross & Co., *Cymbidium grandiflorum* (which fig. 27 represents) caused considerable comment and awakened much admiration. It has large size combined with pleasing colouring. The sepals and petals are of a dull pea-green with brownish dots towards the base. The lip is white, spotted with brown and clearly, although not deeply, margined with green. It is alike distinct and beautiful.

**EVENTS OF THE WEEK.**—Apart from a meeting of the Royal Botanic Society on Saturday, February 25th, but little of horticultural interest will take place in the metropolis during the ensuing week. The Linnean Society meet on Thursday, March 2nd, and the customary auction sales will take place, as specified in the advertisements.

— **THE WEATHER IN LONDON.**—Changeable weather has again characterised the past week. Sunday was fine, mild, and springlike. Monday also proved mild, but with occasional showers, rain falling heavily in the evening. On Tuesday it rained more or less for most of the day, the barometer, as mentioned in another paragraph, being very low. On Wednesday morning snow and rain fell, and at the time of going to press it is damp and cold.

— **WEATHER IN THE NORTH.**—With occasional touches of early morning frosts, a little sunshine, and much rain, the week ending the 14th inst. has been variable, and on the whole unpleasant. The thermometer has ranged from 28° to 42° during the nights. Sunday and Monday were fine for the greater part, but the evenings of both were wet.—B. D., *S. Perthshire*.

— **THE ROYAL GARDENERS' ORPHAN FUND.**—The Secretary of the Gardeners' Orphan Fund informs us that Her Majesty the Queen has been pleased to command that this charity shall in future be called the "Royal Gardeners' Orphan Fund."

— **LOW BAROMETRICAL READINGS.**—There was a remarkable fall in London barometers on Tuesday last. The reading was at one time of the day 28.68 inches, the lowest point attained since November, 1891. Readings such as this are undoubtedly rare, although it is seldom that twelve months elapse without the barometer falling below 29 inches. The lowest barometer readings observed at the Kew Observatory within recent years have been as follows:—1886, December 9th, 28.31 inches; 1884, January 26th, 28.54 inches; 1876, December 4th, 28.38 inches; 1876, March 12th, 28.47 inches; 1873, January 20th, 28.47 inches; 1872, January 24th, 28.34 inches. The lowest barometer readings on record in various parts of the globe are as follows:—In London, a reading of 27.93 inches on the morning of Christmas Day, 1821; over the British Islands generally a reading of 27.33 inches, at Ochertyre (near Crieff) on the 26th January, 1884; and 27.12 inches at False Point, near the southern mouths of the Ganges, on the 22nd September, 1885, this being the lowest authentic reading observed in any part of the world.

— **THE EARLIER OPENING OF KEW GARDENS.**—Mr. Shaw Lefevre, the First Commissioner of Works, has definitively decided against the earlier opening of Kew Gardens. Mr. Shaw Lefevre, in his final letter, stated that the question had been fully considered by the Government in the preparation of the Estimates, but in view of so many other claims on the public purse and the expense which it would involve it was impossible at the present time to entertain the proposal for the earlier opening of the Gardens. The gates, therefore, will still remain closed to the public until mid-day, which many regard as an unreasonably late hour, and the suggestion of the Richmond Town Council and other local bodies was that the time should be altered till ten o'clock to meet the convenience of visitors generally. It is probable that the matter will be brought forward in the House of Commons upon a discussion of the Estimates.

— **PEACH STOCKS.**—Mr. Dean showed me in one of his houses at Titsey Park a large tree of Violet Hâtive of which he remarked that a few years ago he found that it flagged very much, especially in the early morning. The border was examined and found to be in good condition, and all the surroundings were such that no cause for the evil could be discerned. The tree was on a stock worked some 2 feet from the ground; at length, one day it suddenly occurred to him that perhaps it was the stock that was in fault—that, in fact, it was choking or starving the tree because it was too narrow, or restricted a channel for the conveyance of sap. He at once took out his knife and made an incision right through the bark the length of the stock. The result was, he said, that the bark literally opened with a yawn, giving relief that it was evident was badly needed. Since then there has been no sign of flagging.—D.

— **BOTANICAL SOCIETY OF FRANCE.**—We understand that M. P. Duchartre has been elected President, and M. L. Guignard first Vice-President, of the Botanical Society of France for the current year.

— **IMPORTED APPLES.**—According to the latest returns, 209,262 bushels of Apples were imported into this country during January. In the corresponding month of last year the importations of Apples reached 326,826 bushels.

— **GARDENING APPOINTMENT.**—Mr. Edward Parry, for nearly two years general foreman in Downton Castle Gardens, Ludlow, has been appointed head gardener to G. A. Tonge, Esq., Castlemanms, Twyford, Berkshire.

— **FOREIGN POTATOES.**—It is interesting to note that whilst France sent us 83,901 cwts. of Potatoes last month, only 618 cwts. were derived from Germany. During January, 1892, 62,369 cwts. were obtained from France, and but 23 cwts. from Germany.

— **LONDON PANSY AND VIOLET SOCIETY.**—A meeting of this Society will be held at the Guildhall Tavern, Gresham Street, E.C., on Tuesday evening, the 28th February, at seven o'clock. All interested in the matter are invited.—GEO. MCLEOD, *Hon. Sec.*

— **DEATH OF A FAMOUS ORNITHOLOGIST.**—Ornithologists will regret to hear that the Rev. F. O. Morris died recently at Nunburnholme, in Yorkshire, at the age of eighty-two. He was well known as a popular writer on science, and did much to create and foster interest in some branches of natural history, especially in ornithology.

— **JOHNSON'S GARDENERS' DICTIONARY.**—Messrs. G. Bell & Sons announce an entirely new edition of this handy yet copious dictionary. The work, which has been before the public for forty-seven years, has now been thoroughly revised and considerably enlarged under the able editorship of Mr. C. H. Wright and Mr. D. Dewar. It will be issued in eight monthly parts at 1s. each, commencing on the 1st of March.

— **HORNED CINERARIA.**—The enclosed flower, taken from a plant of Cineraria grown by me from home-saved seed, exhibits a peculiarity which I have not before noticed—viz., in each petal two horns appear, recurving, in most cases, towards the centre of the flower. Every flower on the plant exhibits the same peculiarity. I shall be glad to know whether any other instance of this variation from the normal has come under the notice of your readers.—CHARLES E. SHEA.

— **WELLINGTONIA GIGANTEA AS A WIND TREE.**—It would be well if all intending planters of this tree were aware how badly it is adapted for planting in positions exposed to south-west winds. Two specimens were planted in the park here twelve years since, and they are now about 15 feet high. The south-west side of each is very much disfigured, one being entirely spoilt. I have known this tree recommended as being wind-proof, but in my case this is utter fallacy. I find this Conifer enjoys shelter and much moisture.—E. M., *Swanmore Park*.

— **HINTS TO FRUIT GROWERS.**—The Board of Agriculture have issued an illustrated fly-sheet giving useful hints as to the detection and treatment of the Black Currant mite (*Phytoptus ribis*). Complaints as to the prevalence of this mite in the Black Currant plantations have been received recently from many parts of the country. In some districts this infestation has spread so rapidly that at least 50 per cent. of the buds are full of mites, a much larger proportion being affected in one plantation of 20 acres in Kent recently visited. Buds so attacked are rendered abortive, or at least fruitless.

— **WALKLEY (SHEFFIELD) AMATEUR FLORAL AND HORTICULTURAL SOCIETY.**—Mr. W. Hannah, at a recent meeting of this Society, read a practical and useful paper on "Gardening," in which he gave many useful hints on the laying out of flower gardens, pleasure grounds, and vegetable quarters, supplemented with interesting information on planting, sowing, and management of the principal crops in the kitchen garden. Mr. John Haigh presided. Mr. Thos. Gartery of Rotherham, at a subsequent meeting, read a practical paper on "Seed Sowing," dealing with vegetables, hardy annuals, perennials, half-hardy annuals, and tender annuals. He remarked that the subject was a wide one, and could scarcely be adequately dealt with in a single essay. He, however, touched briefly on the importance of the proper sowing of the various kinds of seeds, and pointed out that the seedsman was often blamed for supplying an inferior article when the real reason lay in wrong methods of sowing. Thick sowing he particularly condemned. Mr. W. G. Cuckson (the President) occupied the chair.

— **DEATH OF MR. ERNEST BENARY.**—We regret to announce the death of the world-famed seed grower, Mr. Ernest Benary of Erfurt, who passed quietly away after a short illness on the morning of the 19th inst. Mr. Benary was a gentleman of great business capacity and social geniality, and widespread will be the sympathy with his relatives in their great bereavement. Mr. Benary was seventy-four years of age.

— **FOREIGN FLORA.**—Prof. R. Shimek is now investigating the flora and the geology of Nicaragua, along the route of the canal, under commission from the State University of Iowa. Dr. Terracciano, of Rome, is about to renew his investigation of the flora of Erythrea, the Italian colony on the Red Sea. Dr. K. N. Denckenbach is commissioned by the Natural History Society of St. Petersburg to investigate the flora of the Black Sea.

— **TADCASTER PAXTON SOCIETY.**—At a meeting of the above Society, held last Thursday, February 16th, a paper on "Allotment Gardens" was read by Mr. Clayton of Grimston Park Gardens. The various profits derived from allotments by the holders were detailed, also the physical and social benefits accruing. A unanimous vote of thanks was accorded to Mr. Clayton for the able manner in which he had dealt with his subject. Mr. Jewitt (who is leaving the locality) resigned the position of Secretary, and Mr. A. Garnett was elected to the position.

— **FRUIT AND VEGETABLE TRADES.**—On Tuesday last an influential deputation, representing the growers and salesmen of Covent Garden, Farringdon, Spitalfields, Borough, and other vegetable and fruit markets in London, waited upon the Lord Mayor at the Mansion House to ask his assistance in establishing a benevolent institution and fund in connection with their trades. The deputation was introduced by Mr. J. S. Daniels, and the request was supported by Mr. G. Coleman and others. The Lord Mayor, in the result, accepted the invitation of the deputation to preside at the forthcoming festival dinner of the London Wholesale Fruit and Potato Traders and Growers' Benevolent Society on March 22nd, when it is proposed to bring the scheme prominently before the trade and the public.

— **GLOXINIAS ALL THE YEAR ROUND.**—It is very evident that with ample stock it is easy to have these at command. A sowing of seed made now will give an abundance of plants to bloom through the late summer and autumn. Older tubers now at rest and potted as late as can be, kept cool all the summer, and then placed on a top shelf in temperate house, will retain their leafage admirably all the winter and bloom very early in the spring. Others kept in a higher temperature will bloom all through the winter. Once a plentiful stock of tubers are to be had the grower can employ them much as he desires, if only some be early forced, and others retarded as needed. The facility with which very fine strains may be obtained from seed enables gardeners to have Gloxinias in plenty with ease. I saw some very fine plants on the top shelf of a temperate house the other day at Titsey Park, which will at once begin to bloom abundantly.—A. D.

— **THE MIDLAND COUNTIES CARNATION SOCIETY.**—The schedule for the current year's Exhibition at the Botanical Society's Gardens at Edgbaston, Birmingham, will shortly be distributed, the date of the Show being August 5th. The schedule remains very much as last year, but with more prizes and two or three more classes added. Especial attention is being given to border varieties and to the encouragement of decoration work with cut blooms. The Directors of the Botanical Gardens have placed at the disposal of the Committee two silver and two bronze medals, which will be given to most successful exhibitors, and special prizes are given by friends for Sweet Peas and other flowers also. Mr. Robert Sydenham, Tenby Street, is the Chairman of the Committee.

— **NATIONAL PINK SOCIETY.—MIDLAND SECTION.**—The Wolverhampton Committee are making arrangements for the 1893 Exhibition of the Midland Section of the National Pink Society on July 11th, 12th, and 13th next, in connection with the great summer Show of the Wolverhampton Horticultural Society in the Public Park. Starting with a balance in hand, the schedule has been arranged, giving increased prizes in the class for twelve Pinks, dissimilar; and there is a class for the encouragement of border varieties, six bunches of any kinds, not more than twelve blooms in a bunch. There are also eight other classes for Pinks. Mr. A. R. Brown offers special prizes for his superb new Pink, Amy, sent out last autumn. Mr. Thurstans of Cardiff, a well-known raiser and grower, is the President for the year; and his son, also an energetic amateur, Mr. C. F. Thurstans, Pennfields, Wolverhampton, is Hon. Secretary.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—At the last meeting Mr. W. B. Latham, Curator of the Birmingham Botanical Gardens, read a paper on "Stove and Greenhouse Climbers," alluding to those of special interest, instancing amongst the former *Gloriosa superba*. This the essayist grows in loam, decayed manure, and sand, starting the tubers early, and laying the pots on their side in a warm house during the winter months. *Stigmatophyllum miniatum*, *Thunbergia grandiflora*, *Solanum Wendlandi*, *Mucuna imbricata*, and *Aristolochia elegans* were named as more rarely seen, but beautiful stove climbers. Cultural instructions were freely given, and a good discussion followed.

— **FOURCROYA SELLOA.**—At the recent meeting of the Royal Botanic Society on Saturday one of the branches of the flowering stalk of *Fourcroya selloa* was shown from the Society's conservatory. This is a Mexican plant allied to the Aloes, and like them it flowers only once during its life. The plant, which has been in the conservatory for upwards of twenty years, late last autumn threw up a flower spike which in very short time grew to a height of 30 feet, and passing through the glass roof, rose for some feet into the open air. It could not, of course, resist the frosts and fogs of winter. The flower buds dropped unopened, when immediately from each node a number of young plants appeared. This mode of reproduction is found in only a few species of plants, and is especially valuable in relation to the cultivation of *Fourcroyas* as a source of commercial vegetable fibre.

— **THE KINGSTON AND SURBITON GARDENERS' ASSOCIATION.**—The adjourned meeting of the new mutual improvement association for gardeners was held at the Albany Hall on Thursday evening last, when Mr. T. Cushon presided over a good attendance. The rules prepared by the sub-Committee were accepted after discussion and ordered to be printed, the subscription of gardeners being fixed at 2s. 6d., and honorary members not less than 5s. per annum. The election of President and Vice-President was deferred. Mr. Dean was elected Hon. Treasurer, and Mr. Yeabsley, of Surbiton Hall Gardens, Hon. Secretary, the Committee being chosen as follows:—Messrs. Cushon, Watson, Tibble, Henbest, Benson, Martin, Hughes, Woods, Hawkes, Christmas, Marlow, and Peed. The next meeting will be held on March 2nd, at St. James's Hall.

— **A HUGE EUCHARIS.**—In one of the houses at The Briars, Reigate, the residence of Mrs. Barclay, there is one of the very finest clumps of *Eucharis amazonica* to be found almost anywhere. This giant cluster, for it can hardly be described as a plant, is in one of the largest of pots, for it is some 28 inches across and as deep. The growth in the pot is literally a mass of bulbs and leafage, the latter measuring 8 feet across. It is luxuriantly healthy and perfectly clean. The remarkable thing is that the plant, which some fifteen years ago originated from one bulb, has been in the present pot some nine or ten years, getting such occasional dressings of le fruitier, and guano, as it is possible to apply, and liquid manure. Since the beginning of December forty-nine splendid spikes or clusters of bloom have been taken from it, and about four such crops are furnished during the year. This grand clump reflects on Mr. Bailey, the gardener, the highest credit. It weighs some 4 cwt., and is seldom moved.—D.

— **CLOSE PINCHING AND PLANTING VINES.**—Far be it from me to cross pens with the skilled writers and practical men who have written on this interesting subject, yet I would fain have a few lines. Leaving out of the question the whole scientific value of each leaf, I emphatically protest against the advisability of wild Vine growth. For years I have conclusively proved that heavy crops of Grapes can be successfully produced by a continuous system of close stopping. The simple stopping of any Vine lateral is, as we all know, the stoppage to a certain extent of the flow of sap, but then if this operation is done at the correct time with thumb and finger it must be beneficial; fewer, yet finer, foliage is thus obtained without grossness. A few full-sized leaves are of far greater value than a crowd of smaller ones. The sub-laterals, pinched at one leaf, cause root development. By the end of the season I find ordinary laterals three leaves longer than at the first stopping. This of itself is against close Vine planting. Vines at 3 feet from rod to rod will answer well under this treatment, and Muscats 6 inches wider. Dealing with Vines 2 feet apart, though I crop fairly heavy, and have yearly fair results, these do not equal those of the wider-planted Vines. I treat every lateral as for fruiting all through the season. The result in healthiness of foliage is all that can be desired; and if fruit does not finish it is a question of a rather too heavy crop.—STEPHEN CASTLE, *Fordingbridge*.

— EXPERIENCE IN HEATING.—I see an error in my recent article on page 132. It reads, "Where a large number of houses in one range are all heated at about the same level from the mains, presuming the boiler is fixed in a central position, as it should be, the connections at the bottom of these vertical pipes are often as hot as is possible to bear the hand upon." I did not mean that the heat would not circulate up such vertical flow pipes in such an arrangement, for I should say that it certainly would. I ought to have stated "the connection at the bottom of these tall vertical pipes *here*, &c." That would have made the matter clear, but it was rather difficult to define. A boiler fixed centrally would heat far more efficiently, in my opinion, than if fixed at one end of the garden.—J. J. CRAVEN.

— THE WOLVERHAMPTON HORTICULTURAL SOCIETY. — The schedule of prizes for 1893 has just been issued, the Exhibition to be held in the extensive and well-kept public park at Wolverhampton on July 11th, 12th, and 13th. The schedule is a very liberal one, and large prizes are offered, especially for groups, stove and greenhouse plants, Roses, fruits, and vegetables. The handsome prizes for Roses will be certain to ensure a grand exhibition of this popular flower. Last year the Committee offered prizes for twelve distinct varieties of garden decoration Roses, to be shown in bunches, and two exhibits of great merit, from Messrs. Cooling & Sons, Bath, and Mr. Coombes, The Gardens, Himley, near Dudley, were greatly admired, and these prizes are repeated this year. A handsome gold medal is offered by a local gentleman for the best display of Violas and Pansies, with other medals as second and third prizes, and this is a new feature which will bring out some of the florists from Scotland. The schedule will no doubt secure a splendid show.

— HORTICULTURAL CLUB.—The annual dinner of the Horticultural Club took place on Tuesday evening, February 14th, at their rooms, Hotel Windsor, Victoria Street, Westminster, and there was a larger attendance than on any previous occasion. The chair was occupied by Sir J. T. D. Llewelyn, Bart., and amongst the members present were Messrs. John Lee, Arnold Moss, Philip Crowley, Herbert J. Veitch, J. S. Cousens, C. T. Druery, Geo. Bunyard, Harry Turner, William Bull, George Munro, James Webber, J. C. Wheeler, George Goucher, B. R. Davis, W. Soper, Rev. F. H. Gall, &c. The visitors present were Messrs. Owen Thomas, Her Majesty's gardener at Frogmore; Mr. John Egleton, Clerk of the Fruiterers' Company; and Mr. George Ingram, Secretary of the Gardeners' Royal Benevolent Institution. After the usual loyal toasts the Chairman proposed the prosperity of the Horticultural Club, saying that when he came up from his far off residence in Wales, where he met with but little sympathy in his horticultural pursuits, he had no greater refreshment than these monthly meetings of the Club, where he was sure to meet with congenial spirits, and not only be profited by the discussions, but also enjoy the conversation of those who, like himself, were interested in horticulture in its many branches. The Secretary, in responding to the toast, stated that the Club was never in a more prosperous condition. A considerable sum was invested, and a number of new members during the past year was greater than in previous years. The Club was a social one, and in every respect had been helpful to horticulture. Various other toasts were given, and during the evening an excellent selection of vocal and instrumental music, kindly arranged by Mr. George Bunyard, added much to its pleasures. Mr. Geo. Bunyard proposed the health of the Chairman, which was drunk with enthusiasm, and with musical honours, and the party separated greatly pleased with the success of the evening.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—On Saturday evening last there was an excellent attendance of members at the Museum, William Brown Street, to hear Mr. E. J. Baillie of Chester deliver an address on "Fruit and Flower Farming." Mr. T. White, Chairman of the Association, presided, and briefly introduced the lecturer. Mr. Baillie dealt with his subject in an instructive and humorous manner, both socially and morally. He touched on the land question, drew a striking comparison between steam and hand labour, how best to go about the question of fruit and flower farming with a view to employing the workers over the whole period of the year, the work of technical education, emphasising more especially the good that might be accomplished if the poorer classes in the towns were taught the great value of fruit as an article of diet, and the various purposes to which it might be put. He then dealt with the railway rates, and gave instances of the glaring injustice imposed

by the railway companies. In concluding, Mr. Baillie said that in his opinion until the railway companies met the producer in a right spirit, until the middleman was swept away, and agencies established where fruit of the highest quality could be bought and transferred throughout the country, and where the interests of the producer were thoroughly protected, he held out very poor hopes of those possessing small holdings ever being able to reap the perfect reward for their labours in the matter of fruit culture. Speaking of the love for flowers, he appealed in a most eloquent manner for the love of them to be by every means brought nearer to those poor toiling ones in our towns and cities who scarcely ever see a gleam of sunshine, and where green fields are a thing unknown. Mr. Ranger proposed a hearty vote of thanks to Mr. Baillie for his instructive address, and this was seconded by Mr. Glover. The remainder of the evening was devoted to the selection of varieties of fruit succeeding in the Liverpool district, Mr. R. Pennington promising to read a paper on the subject at a future meeting. A vote of thanks to the Chairman closed the meeting.—R. P. R.

### PANSIES IN WINTER.

IN "Seasonable Hints on Florists' Flowers" by "D., Deal," in the *Journal of Horticulture* of February 16th (page 130), we read, with regard to Pansies, "that these are always difficult to manage in this southern latitude, and I find them very likely to go off during the winter, when, as during the past two months, the frames have to be kept tolerably close; they then damp off, and I have lost a considerable proportion of my plants during the winter."

As a Pansy grower I read these remarks by a good old florist with some surprise, and I fear that if this is the practice of wintering plants in the south something has yet to be learnt. A fair portion of my life has been spent in the south, and I know the great difficulty in keeping Pansies alive in very hot summers, but I never knew any difficulty in wintering them. I was for four years with the late Mr. Charles Turner at Slough when the old show Pansies were in the full tide of popularity, and Pansies in pots were then exhibited as I have not seen them since. I had several years' experience of Pansy growing in Yorkshire, and whilst there was the first to take the Fancy Pansy in hand; and I am still a grower here, in a smokey suburb of Birmingham, and my plants do not get any sunshine whatever upon them from November until March. The plants, probably 2000, are as healthy as young Cabbage plants in spring, and I will briefly describe the treatment accorded them.

I use frames for wintering, placing about 6 inches underneath the soil a layer of soot to prevent worms getting through, as they are a deadly enemy to Pansy cuttings by drawing them into the soil. The soil is made up firmly to within about 6 inches of the glass back and front, the cuttings inserted at any time in the autumn, not shut up close for more than a day or two if bright, and slightly shaded, but air always afforded afterwards, and kept watered if dry warm weather prevails. In September and onwards I put them in freely without having the lights on at all. The young plants have had an abundance of exposure, merely keeping the lights on in very severe weather, or when we have continuous rain, but always with air freely admitted, especially in wet weather. We are now having mild but almost continuously wet weather, yet the lights are constantly off, and will not be put on again until we blistering east winds or very severe frost.

The Pansy is essentially a hardy plant, and nothing ruins it quicker than coddling it. Of course it is essential that healthy strong cuttings or young healthy offsets should be secured. I do not recommend keeping the plants in pots in the winter. They are much safer planted out as close together as may be required, and kept hardy; and when transplanting or potting the plants can be lifted with good balls of earth. I cannot too strongly recommend early planting out, in March if possible, and place the plant a little deeper in the earth than it was in the frame.

Here, even in our wretched climate compared with that of the south, plants frequently stand putting well in the open, and one of my Pansy growing friends last year had a batch of his finest varieties out of doors without any protection—and it was a terrible winter—and they did far better than plants in frames, which had been kept too close. In the south coast district there should be no difficulty whatever in wintering Pansies without losses if planted out, but I know from experience how difficult it is to keep Pansies and Violas in good health, and sometimes alive in very hot weather. I may add that the same treatment does for the bedding Violas, and purchasers should insist on plants being well rooted with earth about them, and each packed separately in damp moss.—W. DEAN.

### BEGONIA GLOIRE DE SCEAUX.

FOR the embellishment of well heated conservatories and other glass structures during the dull period of the year few plants can surpass some of the winter-flowering Begonias. When properly managed most of the old varieties of these will give a profusion of bloom all through

the winter, but far superior to many is the beautiful Gloire de Sceaux (fig. 28). This Begonia is of French origin, and is said to have been raised by Messrs. Thibaut & Keteleer of Sceaux. For decorative pur-

time, not only recommended a silver Banksian medal for the exhibit as a whole, but adjudged a first-class certificate.

This Begonia is quite distinct from others in cultivation, and well

FIG. 28.—BEGONIA GLOIRE DE SCEAUX.

poses it is most valuable. This fact was clearly demonstrated by the splendidly grown plants exhibited by Mr. Jennings of Ascott, Leighton Buzzard, at the Drill Hall, on January 17th. On that occasion the Floral Committee of the Royal Horticultural Society, as reported at the

gown plants of it are very effective. It is upright, but compact and vigorous in growth, producing ample dark bronze-green leaves. The flowers are pink in colour, and are borne in large clusters well above the foliage. It is a plant that should be seen in every garden.

## AN AMERICAN NOTION.

MESSRS. PITCHER & MANDA in offering Chrysanthemum seed (in their English catalogue, Hextable, Swanley) saved in their nurseries, New Jersey, U.S.A., also offer a first prize of £20 for the three best varieties raised by purchasers of seed for the three best varieties to be exhibited at the N.C.S. Show at the Westminster Aquarium in November with £10 and £5 for the second and third best varieties respectively, the prizewinning plants to become the property of the donors of the prizes.

## DWARF PLANTS.

It is pleasing to see the great advance made in raising varieties that produce large blooms on dwarf plants. Last year we had Vivian Morel not more than 4 feet high, and carrying fine blooms. For the information of those who wish to add dwarf-growing varieties to their collection I append a few names as they occur to my memory:—Mrs. Faleoner Jameson, orange bronze; Mohawk, chestnut red and tipped gold while young; Mons. Bernard, purple; Mrs. E. D. Adams, creamy white and tinged pink; Mrs. F. A. Spaulding, ochre yellow shaded bronze (I cannot see any difference between this and J. Stanborough Dibbens); Comte F. Lurani, white ground, heavily veined and mottled rose; W. H. Lincoln, deep yellow, a decided improvement upon grandiflora; and Marquis de Paris, white. The above are comparatively new varieties belonging to the Japanese section.

Two years since Mr. Molyneux exhibited blooms of several varieties of the "Queen" family at the Kingston Show, and these were quite as fine as any in the competition classes. He also showed parts of the main stems which had produced the blooms, which were of less size than the small finger of a man's hand; the plants were not more than 4 feet in height. I noticed too that the wood from which the blooms were cut was very hard. It seems to me that there is much yet to learn how to secure high-class blooms of naturally tall-growing varieties from plants under 4 feet high, and still obtain them from "crown" buds.

## SEPTEMBER VARIETIES OUT OF DOORS.

What a pity these are not grown more extensively for flowering in the borders during the autumn. Apart from their usefulness in a cut state they brighten up the herbaceous borders at a time when the regular occupants are waning. Madame Desgrange is as good as any, the white blooms being always admired. Mrs. Hawkins, deep yellow; Gustave Wermig, pale yellow; and Mrs. Burrell, sulphur yellow, are also well suited for the purpose. The new Lady Fitzwygram ought to prove useful where a whole bed of Chrysanthemums is required. The habit of growth, low and spreading, should render it more desirable for beds than borders. Its pure white freely produced blossoms are of good form.

## SINGLE-FLOWERED VARIETIES.

At last this section is receiving increased attention. Not only are the single varieties much more showy when arranged in clusters than the ordinary incurved section, but they make a welcome break in the long rows of the stiff formal blooms at exhibitions. The colours are extremely diversified, and varieties like Oceana and Jane are always admired. It is surprising to what a huge size some varieties will grow when the plants are cultivated with the express object of producing the largest blooms. I have seen the variety Admiral Sir S. Symons grown in this way, giving single blooms measuring 8 inches in diameter. Such results, however, are not desirable.

The true way of showing off this section is by setting up in bunches long spikes with all their blooms developed, disbudding being rigorously dispensed with. Another advantage which these single flowered sorts possess over any other is the easy way they can be cultivated really well in exceptionally small pots, thus rendering them so much more useful for the decoration of the dwelling house.—SADOC.

## PROFITABLE CHRYSANTHEMUMS.

I HAVE been much interested by the remarks of your correspondents on this subject. The varieties described by "Enfieldian" (page 117) are I know most suitable, and find favour with the majority of the growers. I fully concur with his judgment as to the superiority of Madame Louise Leroy over the well-known Elaine; but I would here point out that "circumstances alter cases." Surely "Enfieldian" knows why Elaine secured the highest returns last season. At least I should have thought that every grower in the Lea Valley would have an idea as to the true facts of the case. It will be well within the memory of your readers that we had a severe frost on September 18th, which caused dire havoc amongst the early plants. If I say 100,000 plants were crippled in the Lea Valley alone I should be well within the mark, and at the same time it will serve to show this portion of the supplies were cut off. As a natural consequence prices ruled high, and it was no uncommon thing to pay 9s. and 12s. per dozen bunches for Madame Desgrange—bunches that could be obtained the year previously for 3s. per dozen.

Elaine followed the Desgrange family while the prices were still high, and of course realised a good figure. The moment Madame Louise Leroy, Mdle. Lacroix, Florence Percy, and Fair Maid of Guernsey came on the scene, however, down came the prices, so they could be obtained at 4s. and 5s. per dozen bunches. So the prices obtained last year for Elaine must be considered exceptional.

Fashion has much to do with regulating the prices of different colours. For instance, last season yellow was almost as much in demand as white, and prices were high accordingly. I am not surprised to hear that Mons. Bernard failed to establish a position on the market, for few would wear such a colour. This season, however, sees a change, and the very colours which were at a discount will now be appreciated. Such is the fashion that rules the market colours and prices. I should like to ask if any of your readers grow Mrs. Carey (yellow)? Nearly all market growers cultivate the white form, but as far as I can ascertain the yellow form comes from the Channel Islands only. All through January there was an enormous supply from Guernsey. A friend of mine has now established a pink form of Mrs. Carey which I believe will prove useful. I am trying a few plants this season, so I shall be able to report thereon.

Louis Boehmer will become a marketable variety, for, when grown on market principles, its character is considerably altered. The blooms are reflexed instead of incurved, the colour seen in large blooms is changed for a much more delicate shade, and its hairy character less prominent. The variety is so vigorous, and has the facility of developing every bud, after the style of La Triomphante, that it cannot fail to become a prime favourite. Mr. Divers some time ago called attention to its adaptability for growing in small pots. I can also strongly recommend it for this purpose. I rooted about two hundred cuttings in boxes last June and grew them in 6-inch pots. They were pinched once, so that good bushy plants were formed. I am so satisfied with the result obtained that the variety will be grown on a larger scale in future.

I quite agree with "Enfieldian" in his remarks as to the Val d'Andorre type for cut flower purposes. As pot plants they are simply invaluable, but all such varieties that have very little stem above the foliage are practically useless for market purposes, and they are much too stiff.—JAS. B. RIDING, Chingford.

## NATIONAL CHRYSANTHEMUM SOCIETY—ANNUAL MEETING.

THE annual meeting of the members of this Society was held on Monday evening last at Anderton's Hotel, Mr. R. Ballantine presiding. The whole of the officers were present, and there was an exceptionally large attendance of members, which would probably have been much greater but for the rain which fell heavily for an hour before the time appointed for the meeting.

The minutes of the annual meeting held on March 15th last year were read, and the Chairman observed that there was only one item that called for explanation upon them. Mr. Leopold de Rothschild on that occasion had been chosen the President of the Society, but being unable to accept it the Committee had applied to Sir Edwin Saunders, and he was sure they could not have chosen a better man. Sir Edwin had attended several of the Society's meetings and evinced much interest in the proceedings of the Society, and he felt sure the meeting would approve of the selection.

The Secretary then submitted the annual report and financial statement for the past year, by which it appears that it has been one of the most prosperous the Society has had. Numbers have steadily increased; a large accession of affiliated societies has taken place, there being now 620 members and 100 societies at home and abroad in affiliation, showing an increase of fourteen during the year. The November show was highly satisfactory, the competition for the Holmes' memorial cups being very keen. Mr. Earland's frozen blooms from New Zealand had drawn considerable public attention to the Society, and in order to return the compliment it had been decided to send out some English prize-winning flowers to the colony for exhibition there. In the ensuing year there are to be three shows held by the N.C.S.—viz., one in October, November, and December, the ordinary September show being taken over by the Royal Aquarium Company. Reference is also made to the Conference on show boards, and the reason that led the Committee to make no alteration for the present. The Society's receipts for the year amount to £944 14s. 3d., of which £209 15s. 7d. was members' subscriptions, £163 13s. donations and special prizes, £291 16s. amount contributed by the Aquarium authorities, and £49 7s. affiliated societies' fees. The expenditure has been heavy, and in spite of previous anticipations has swallowed up the entire revenue excepting a few shillings. The chief items on this side are prize money at the September, October, and November Shows, with some arrears of 1891, £429 16s.

The Secretary explained the reason why the expenditure had been somewhat heavy, and pointed out that the members' subscriptions were a small amount when compared with the outgoings. He hoped every member would see the importance of introducing new members, as the loss by resignation and removal amounted to about seventy or eighty members per annum.

The Chairman moved that the report and financial statement be received and adopted. The work of the Society had met with the approval of the gardening press, and with respect to the correspondence in one of the gardening papers he was able to say that an accession of members was distinctly traceable to that cause.

Mr. E. C. Jukes thought the report was really more favourable than it appeared to be. Upwards of £40 was due by affiliated societies, and

had that sum been paid the National Chrysanthemum Society would that night have been in a good position. It was not creditable for members to be in arrear, still less, he thought, was it creditable for affiliated societies not to pay their dues. Considering what a bad year 1892 had been for all in trade, he thought the balance-sheet showed the Society was in a flourishing condition.

The Secretary explained that arrears amounting to £11 19s. 6d. had come in during the past week, but that there were still sixty-eight defaulting members. He then read the following list of special prizes for the forthcoming shows—Messrs. Pitcher & Manda, £35; Messrs. Sutton & Sons, £20; Mr. Owen, £12; Mr. H. J. Jones, £9; Mr. Godfrey, £7 7s.; Messrs. E. D. Shuttleworth & Co., £5; Mr. E. C. Jukes, £5.

The election of officers next occupied the attention of the meeting, with the following result: President, Sir Edwin Saunders; Treasurer, J. R. Starling, Esq.; Chairman of Committee, R. Ballantine, Esq.; Vice-Chairman, E. C. Jukes, Esq.; Secretary, Mr. Rd. Dean; Foreign Secretary, Mr. C. Harman Payne. The Dowager Duchess of Sutherland and Lady Saunders were added to the list of Patronesses, and to the list of Vice-Presidents and Patrons the names of Lord de L'Isle and Dudley, Sir Trevor Lawrence, and others.

At this stage of the proceedings, and after the officials had thanked the meeting for their re-election, the Secretary read a telegram from Mr. Goodacre nominating Mr. Blair, Mr. Mease, Mr. Woodgate, and Mr. Lambert as members of the General Committee. Mr. C. E. Pearson, who had become a member of the Society, wished also to be nominated, but inquiry was immediately raised as to whether these gentlemen would be able and willing to attend to the work if elected. Mr. Mease not being a member his name was withdrawn; and after the nominations were all given in it was found that there were twenty-two candidates for the twelve vacant places on the General Committee. The successful ones were Messrs. H. J. Jones, J. H. Laing, Boyce, C. Gibson, G. Stevens, Geo. Gordon, E. Beckett, D. B. Crane, Wright, B. Wynne, Mardlin, and Davey, the whole of the retiring members who, being eligible for re-election, being again elected. Mr. Arthur Veitch and Mr. G. J. Ingram were tellers.

Mr. W. H. Fowler proposed a vote of thanks to Sir Edwin and Lady Saunders for the interest they had shown in the Society during the past year, and the Secretary moved one to the Catalogue Committee.

The rules of the Society next came on for discussion, and it was evident that Mr. Addison's motion for a rule to enable members to be expelled for improper conduct excited some curiosity. In opening the discussion, Mr. Addison said it would require very little argument on his part to persuade the meeting that it was necessary some such rule as he proposed should be incorporated in the constitution of the Society, it was nothing unusual, and was one that might be found in all societies and clubs in and near London, and he had framed it from several of such societies' rules. He would read it:—"That any member who shall refuse to conform to the rules and regulations of the Society, or shall be guilty of irregularity or of dishonourable or disorderly conduct, or of conduct likely to bring discredit upon the Society, shall be subject to expulsion by a vote of two-thirds of the members present at any general meeting." In support of the proposal he would take only a few points. There were nearly 700 members, and as the Society stood, if a man were elected a member and also elected on one of the committees he could remain in that position for three years, no matter what he chose to do. Mr. Addison, in support of his contention, quoted a case of a member who had sold tickets and not accounted for them, against whom they were powerless, and the same rule would he thought legalise what the Society had hitherto done in removing the names of members whose subscriptions remained unpaid at the end of the year. Mr. W. Wells seconded the motion, remarking upon his own case, which the Chairman prudently ruled out of order.

Mr. E. C. Jukes strongly opposed the motion, although he gave the mover every credit for bringing it forward in the interest of the Society. The case of this Society was not analogous to that of cricket clubs and other similar organisations. Where such a rule was in force the persons joining knew of it, and they accepted the condition. Irregular conduct was difficult to define, and no two men agreed in their definition of it. In the City he saw every day men doing what he personally would not like to do, yet these men were perfectly satisfied. He was quite as much opposed to improper conduct as anyone present, but it would be dangerous to leave such a definition in the hands of a public meeting.

Mr. Fowler could not see his way to support the motion as it stood. If members could be struck off the roll for non-payment of their subscriptions, he thought something might be done. Mr. Beavan supported Mr. Fowler, and thought the proposition would lead to trouble. Other speakers against the proposal were Mr. Hicks, Mr. Rd. Dean, Mr. W. Piercy, Mr. Newell, Mr. Geo. Gordon, and Mr. Moorman, the last of whom hoped the mover would see his way clear to withdraw it altogether.

Mr. Addison, after the opposition, said that in withdrawing his motion he hoped the members would give him credit for honestly believing he was acting in the interests of the Society by adopting the course he had. He thought that Mr. Fowler's observations if embodied in a proposition to follow would satisfy him equally well as his own motion.

Mr. W. H. Fowler then moved a resolution to the effect that members who had not paid their dues by a given date should be struck off the register, and this was carried.

New members were elected, and the business of the evening brought to a close at an unusually late hour.

## CELERY AND ITS CULTIVATION.

[Read by MR. R. FILKINS, at the Chislehurst Gardeners' Society.]

MOST gardeners desire to have a good supply of that excellent winter vegetable Celery, and yet few obtain a really good crop. The question naturally arises, Why is it? Now, from my own observations there are three primary evils that militate against a good sound crop—bolting or running to seed, soft and pithy growth, and the attacks of the Celery fly or maggot. I have no hesitation in saying that the gardener is in most cases to blame, because he does not always study the requirements of the plant.

In Nicholson's "Dictionary of Gardening," the Celery is described "as a native British plant of biennial growth found in a wild state inhabiting marshy places." It has a number of fibrous roots and very succulent stems, and requires a large amount of moisture to keep up the supply of necessary sap. It is also essential that the plant should have as many perfect leaves as can be exposed to the sunlight. The necessity of this will be apparent if we consider what the leaves of a plant have to do; it is only through the foliage that plants obtain the carbon that forms the greater part of their dry material. This carbon is taken up by plants as carbon dioxide from the air; in the chlorophyll cells it is decomposed and separated, the oxygen is given off into the air, and the carbon retained. Combined with hydrogen and oxygen it forms starch for building up the tissues of the plants, but this can only be done under the action of sunlight and heat.

I have said that the gardener was to blame for the three primary evils attendant on Celery growing, and I will endeavour to prove it. In the first place, he sows his seed too soon and too thickly. In some gardens space is limited, and Celery has to be planted out after early Peas and Beans come off the ground, which does not generally take place till the middle of July, and if the seed is sown at the end of February or beginning of March the plants are either kept too long in the seed pan, or if they have proper attention in the way of pricking out the plants will be too large to bear moving into their permanent position without giving them a check. Another disadvantage of too early sowing is that the crop is at its best before it is really wanted. Celery is not usually required in very great quantity before the end of October, and to have this properly blanched it should be ready for earthing up at the beginning of September. This, however, would not be in such good condition to stand the frosts of winter as later plants, coming to maturity at the middle of October.

In the manner of planting also the grower is sometimes greatly to blame, the usual practice being to dig out a trench a foot deep, putting the good top soil between the trenches. He then digs in manure, and in doing so brings up soil which is unsuitable. Then the plants are put out, and they grow very freely for a time, owing to the manure; but as soon as this is exhausted the roots push out in search of food, but instead they are walled in as it were by ungenial soil, owing to the depth at which they are planted. It is often, too, at this stage of their growth that the plants are most neglected in the matter of watering. The gardener forgets that it is a ditch plant, and although he has provided the ditch he neglects to give the water.

In the foregoing remarks I have endeavoured to show how the gardener is to blame for pithy and bolted Celery by early and thick sowing, and by giving it too many checks during its growth. One of the greatest checks is not supplying sufficient water after the plants are put out, which to a very great degree predisposes them to the attacks of the Celery fly or maggot, as owing to an insufficiency of moisture the tissues of the plants are not properly built up, the cuticle of the leaves is much softer, rendering them less able to withstand the attacks of enemies. Anyone can prove this by leaving a few plants in the bed they are pricked-out in, and withholding water. As soon as they have exhausted the goodness of the soil the maggot will make its appearance, simply because the plants are starved, and in a debilitated condition. But Celery that is kept continually and steadily growing from the time the seed is sown till cold puts a stop to growth is very rarely attacked by maggot, and then only on leaves that by being shaded are not so robust. "Yes," someone may say, "but that requires much attention." That Celery growing does require attention I admit, but sound cultivation is all that it requires. If you are able to devote a part of the garden to Celery then give it careful preparation; trench the ground as deep as the soil will admit, incorporate with it some manure, the ashes from a rubbish fire, the refuse from the potting bench, leaf mould, are all good; but the soil from an earth closet I consider the best, as it contains a large amount of nitrogen and phosphates. Whatever is used well mix it with the soil, frequently forking it over so that it is well pulverised and exposed to the action of the weather.

If an early supply is wanted sow the seed thinly early in March, and place it in a temperature of from 60° to 65°. When the seedlings are up place the pan or box as near to the glass as you can, so that they can get plenty of light.

In from five to six weeks the seedlings will be ready to prick off, which should be done into deep boxes filled only so full of soil that a square of glass placed on the box will not touch the plants. They should be well watered so as to moisten all the soil, the glass put on, and if necessary a piece of paper to shade them. The reason for putting the glass on is to prevent evaporation, and it does away with the necessity of frequent waterings. After three or four days the glass may be tilted up so as to give a little air, and a slight dewing with the syringe should be given. Gradually harden them, and by the middle of May they may be transferred to the trenches. These should not be more than 4 or 5 inches deep, and water the plants well. I do not believe in driblets,

rather give one thorough good soaking that will last a week than five or six surface dribblings that only coax the roots to the surface to be shrivelled by the sun. After watering, as soon as the top is moderately dry, run the hoe through, so that the surface dries, as this layer of dry soil prevents evaporation, and also prevents many valuable gases leaving the soil.

About the middle of July a little soil should be chopped from the sides of the trench to cover any roots that may be pushing to the top. A dressing of soot should also be given, as this prevents slugs eating the plants, and it also improves the colour, and gives a dark green appearance to the foliage. By the end of August the plants can be earthed up. Be careful to keep the soil out of the hearts. A week before earthing up go over the plants, and all the small leaves and any suckers there may be taken off, as this gives time for the fractures to dry and heal. Before earthing up I generally tie each plant with a piece of matting to keep the soil out of the heart, taking it off after earthing; in six weeks the Celery may be used.

For the main crop the last week in April is soon enough to sow the seed. If a large number of plants is wanted make up a very slight hot-bed, on which place an old frame in which to sow the seed. Sow the seed very thinly, and when the seedlings are up ventilate freely in all favourable weather. When the plants are large enough prick them out on a bed of prepared soil. This bed should be in a sunny spot, and ought to be made up of two parts loam, one part decayed manure, one part leaf soil with plenty of road grit, thoroughly mixing it. Tread it moderately firm, water the plants and shade for a day or two, keep them well supplied with water when established, and they will lift from this bed with good balls of soil attached to the roots.

The best position for the plants is a piece of ground from which a crop of Peas or Beans has been taken. The only preparation the ground will require is to draw wide drills from 3 to 4 inches deep at 4 feet apart in which to place the plants, and keep them supplied with water till October. Frequently stir the soil between the rows, sprinkling soot or nitrate of soda over the ground before hoeing. Do not earth the plants up till severe frost compels it for protection. After earthing, if it is very frosty, protect with some dry litter or bracken, and if some boards nailed together can be placed over this it will be made more secure.

Perhaps it may not be generally known why it is that Celery always does so well after Peas or Beans, especially if the ground has been trenched. Science has found out that soil that has not been broken up and exposed to the air contains more free acids—ferric and nitric acid, which are not taken up by plants until they have been converted into nitrogen. The roots of all leguminous plants have the peculiarity of doing this, leaving the ground richer in nitrogen than when they were sown; this the Celery is able to appropriate. Another advantage of Celery following early Peas is that they get an open situation, so that they get all the advantage of light and air. Being in shallow trenches the roots are influenced more by the sun and air. The ground also being firm the growth is more solid and better able to stand the frost of winter.

I have grown Celery for a late supply upon ground from which crops of Peas and Beans have been taken without any further preparation beyond hoeing to loosen the surface for planting. The ground was bastard trenched and plenty of manure put in for the Peas and Beans. The Peas were sown 10 feet apart with three rows of Broad Beans  $2\frac{1}{2}$  feet asunder. After these were removed rows of Celery were put out between where the former rows had been at a distance of 5 feet apart. The plants were kept well watered, and after they were well established supplies of house sewage were given. No attempt was made to earth up till nearly the end of October, when it was done at one operation. Out of 300 plants not one bolted or was pithy, and with the exception of a leaf here and there practically free from maggot. With the precaution of covering with dry litter on the approach of severe frost I was able to keep up a supply till the end of March.

For an early supply I used to set apart a plot of ground, the only part of the garden from which I could get a good crop of Carrots. One half was occupied by Carrots and the other half Celery. After the Carrots were taken off the ground was manured with soil from an earth closet, stirring the ground deeply, and left rough all the winter. About the middle of May the ground was chopped over, and wide drills, 4 to 5 inches deep, were drawn out 4 feet apart. After the Celery was planted other drills were drawn between and Lettuce seed sown. The Lettuce plants were used before the Celery required all the soil, the Celery coming off in time for the ground to be prepared for Carrots. No manure was added except some soot and wood ashes. Before the soil was chopped down, and being near the sewage tank, the Celery was always given a good supply, but I was careful to have the ground moist before giving the liquid, as I once spoilt a row by giving strong sewage when dry.

I was first induced to think over firm ground for Celery when I went into a nursery in Lincolnshire, where vegetable growing for market was largely practised. A piece of ground was heavily manured and ploughed. In the spring it was well pulverised and sown with Radishes; as soon as they were large enough they were sent to market. When the ground was cleared two furrows were ploughed out where it was intended a row of Celery was to go; the bottom was then dug over, and the Celery planted. The plants had been prepared by making up a large heap of manure in a sheltered corner, and covering it with soil. At the end of March the seed was sown very thinly, and a thick covering of dry Asparagus tops placed on the bed. This was taken off as soon as it was

seen the plants were coming through the soil. When the seedlings were large enough they were pricked out on a piece of prepared ground and ultimately planted out, and no one could wish for better Celery.

Since that time, both from my own observation and from what I have read of the experience of others, I am still of opinion that firm ground, provided it is fertile, is the best. The growth may not be so rapid as when it is grown in a trench of manure, but it is more solid. Another advantage of firm ground is that it does not dry so quickly as loose, light ground, and does not require so much labour in applying water.

I have said nothing about Celery for exhibition. Perhaps at some future time I may take the pleasure of saying something, but I suppose a paper is not complete without saying something about varieties. Of white varieties for some years I grew nothing but Sandringham, but whether from want of care in selection it appears to me to have deteriorated. Carter's Solid Ivory White is good, but it takes a long time to blanch properly. Barr's Covent Garden White is the one I prefer for earliest; it is quite as good a grower as Carter's, but the stems are very much whiter, and the heart comes well up and is quickly blanched. Barr's Champion White I have found good for a main crop. Of red varieties Major Clarke's I have always found reliable. Barr's Covent Garden Dwarf Red for putting out after Peas, is also good. Standard Bearer is useful, but I have not found it so hardy as Major Clarke's or Leicester Red.

In this paper I have given my convictions from practice and observations, but to show that I am not alone in my theory as to firm soil for Celery I may mention that a writer in the *Journal of Horticulture* for August 18th, page 145, gave it as his opinion that Celery could be sown where it was to remain. That Celery will bear planting out into trenches very small I have seen several instances, but in all cases they have had great attention to watering and shading.

In conclusion, let me say that if quick growth is wanted nothing is better than a slight sprinkling of nitrate of soda. Clay's fertiliser is also a good stimulant, being careful to water it well in.

#### PRIMULAS AT FOREST HILL.

A CALL at Messrs. Carter & Co.'s nursery in Houston Road, Perry Hill, which is within comfortable walking distance of Forest Hill station on the London, Brighton, and South Coast Railway, would be well rewarded, for their large collection of Primulas is, or was a week ago, in remarkably fine condition. Passers-by possibly survey with mixed feelings the large house of Cactaceous plants which is seen from the roadway according as their tastes may incline them to regard favourably or otherwise these curiosities of the vegetable kingdom, but there can hardly be two opinions among those who pass in and inspect the Primula houses, brilliant with the collective beauty of some thousands of plants. Persons nourishing strong diversities of taste would surely find common ground for admiration there. Seldom in the many years during which the Holborn firm have been engaged on the popular winter florists' flower have they had so fine a display as this season, and the interest of the collection is greatly strengthened by the inclusion of several novelties of exceptional beauty and promise. It is true that fertilisation is in full swing, and this means that many flowers come off daily; but the quantity is so enormous that now, and for some little time, there will be a rich display of blooms to delight the visitor.

One of the first impressions to follow the preliminary feeling of admiration will be that of speculation as to the serious object of the magnificent show provided. It cannot be for ornament alone, and as for seed, there would seem to be plants enough to provide sufficient for the whole country. It is not easy to appreciate the fact that every seed which can be raised is wanted, and for retail orders alone, not only, however, is such the case, but although many pounds are raised every season the collection has to be annually enlarged in order to keep pace with the growing demand. This might well "give pause." To retail Parsnips by the pound is nothing, but when it is borne in mind what the average size of a packet of Primula seed is, and the immense number into which a pound of seed is split up, it is difficult to realise that that quantity goes but a little way in supplying customers. The fact is Messrs. Carter and Co. not only have a stupendous general connection in seeds, but a special additional one in Primulas, to which they have given more than ordinary attention and prominence.

Primula growers are now a numerous body, and will doubtless be more interested in remarks on the individual varieties than in further generalities. The time has not long passed since cultivators were satisfied to grow the red and white varieties alone, or even to rely upon a packet of mixed seed for their stock of plants; but named varieties have been introduced so far in advance of the old rubra and alba that the former order has changed, and Primula lovers extend their collections so as to embrace as many as possible of the improved forms. The Holborn specialists have been active in catering for them, and the excellence of their strains is now abundantly manifest.

Reference may first of all be made to the singles, which embrace a considerable diversity of colours. The first to be noted in the first house entered was the original Holborn Blue, which excited so much comment when first introduced. It is now well known and widely appreciated; but it has a neighbour which many visitors will consider eclipses it, and that is the variety known as Holborn Porcelain. This is a really splendid Primula. In quality of flower there are few to equal it. The blooms are 2 and  $2\frac{1}{4}$  inches across, beautifully fimbriated and of great substance. They are altogether larger and finer than the old variety, and the colour

is richer ; there is more than a suspicion of purple in it. Though the plants were young, they were carrying good trusses. Altogether the variety may be considered one of the best yet raised. Holborn Magenta is very fine in its colour. It is rich and striking, besides carrying a good truss. Holborn Vermilion is somewhat smaller in bloom, but has dense clusters of flowers. Its hue is a particularly brilliant and telling one. Holborn Queen is wonderfully pleasing. It is a white, with a very faint blush tint, having a good even truss and medium-sized blooms. Holborn Rose is not so striking as its more brilliant sisters, but its colour—rosy pink—is eminently pleasing, and the flower is large. It is a Fern-leaved variety. In Holborn Venus we have a striped and spotted flower, the groundwork being white and the colouring rosy magenta. There are two Holborn Elaines, one Palm and the other Fern-leaved. Both are pure white and both beautiful, but the latter is usually the more admired. It is a beautiful variety, the blooms being large, substantial, and well shown up by the brown stems. In the estimation of many persons this ranks as one of the best in the whole collection. Holborn Salmon is a fine deep salmon with an excellent truss. It is a late bloomer, not yet at its best. Holborn Carmine is particularly rich in colour, and its fine trusses are borne well above the foliage.

The novelties include a really remarkable variety named Holborn Blush. In size and substance of bloom it is one of the finest Primulas ever raised. The petals are quite leathery in texture. The variety is the result of a cross between the blue Holborn Porcelain and the white Holborn Queen, the former being the pollen parent. A happier union was never effected. The new form has the large proportions and beautiful fringing of Porcelain, with even increased size, many of the flowers measuring 3 inches across, and it has the light foliage of Queen. The colour, as will be gathered from the name, is distinct from either parent. The stock of plants is now small. Should the variety prove capable of developing a good truss without losing materially in quality of bloom, it will soon find its way to the position of head of the collection. Another meritorious novelty is the Palm-leaved Holborn Rose, which is the result of a cross between Porcelain and Magenta. It has the shape and substance of the former, but a larger flower than either, and the colour is a bright rose. While not quite equal to Blush, it is a not unworthy companion to it. Holborn Ruby is a curiosity. It has large substantial ruby red flowers, dotted with patches of white, as though they had been splashed with whitewash.

There are half a dozen double and semi-double flowers well worthy of mention. The first is Princess of Wales, white dotted and flaked with rosy carmine. It might be described as a double form of Venus. Lilac Queen has full blooms and a fine truss, the colour being deep lilac mauve. Blue Rosette has double and semi-double flowers of a clear lavender hue. Snowflake is a remarkably free bloomer. The flowers are white, but with a very faint tinge of pink. Prince of Wales, rich rosy salmon, is free in blooming, and very bright in colour, altogether a charming variety. Carmine Empress produces abundance of medium-sized blooms, and in colour it is one of the richest of all, showing up prominently amongst all the others.

#### APPLES DR. HARVEY AND WORMSLEY PIPPIN.

"A. D." (page 130) invites me to send samples of six fruits of each of these Apples to the next Committee meeting of the Royal Horticultural Society at the Drill Hall. I am sorry I cannot oblige him this season, as the demands of the kitchen have cleared away all the fruit of these varieties. "A. D." has, however, had ample opportunity, and doubtless will have again, of comparing the Apples in question. The Journal of the Royal Horticultural Society, vol. x., 1888, on British Apples, states that the Apples named Dr. Harvey, Wormsley Pippin, and Waltham Abbey Seedling were exhibited both in 1883 and 1888, and the Fruit Committee considered Golden Noble synonymous with Waltham Abbey Seedling. Although the members of the Committee act to the best of their knowledge for the time being, they are liable to be proved wrong, even by "A. D." himself, as he remarks that Golden Noble has long since been proved to be distinct from Waltham Abbey Seedling.

I thoroughly agree with him that Golden Noble is a very distinct variety, and worthy of extensive cultivation, either as a standard or on the Paradise stock for bush culture. At some future time, if required, I may perhaps send samples with wood and leaves attached to the Editor of the *Journal of Horticulture*. The description given in the list of British Apples, vol. x., 1888, of the three differently named Apples is almost identical as regards shape, colour, season, and quality. Whatever one may prove, there is not the least doubt that the Apples in question will continue to be grown under their local names in certain districts. In the East of England—Norfolk—Dr. Harvey is extensively grown. The name is commemorative of a learned doctor who lived in South Norfolk and grew the Apple extensively. In the West of England it will always be called the Wormsley Apple.—JOHN CHINNERY.

[There is not the least necessity to send samples of Golden Noble and Waltham Abbey Seedling here for showing the distinctness of the two varieties. The essential points of difference are clearly pointed out in the "Fruit Manual," and Dr. Hogg says, referring to the last named variety, "I know of no Apple which bears fruit so large and has foliage so small." We also know it would be impossible that the present Fruit Committee of the R.H.S. would give anything like a unanimous vote, declaring Golden Noble and Waltham Abbey Seedling synonymous, and the members would be much more likely to laugh the proposition off the table.]

#### GILIA BRANDEGEL.

THE annual Gilias are better known and more extensively grown than the biennial and perennial forms, though some of both of the latter are worthy of a place in every garden. *G. Brandegei*, the perennial species represented in the engraving (fig. 29) forms tufts of small peculiar and pretty leaves, alternate on the leafstalk ; the flower stems are erect, from 6 to 8 inches in height, giving a succession of bright primrose-yellow flowers all through the summer and autumn. It is perfectly hardy, and seems to flourish best in a damp shady situation ; if on rockery the natural drainage will be

FIG. 29.—GILIA BRANDEGEL.

found sufficient. Planted out in a position where it can be treated liberally it attains a large size for a Gilia, forming in one year a clump from 1 to 2 feet in diameter. The young growths or side shoots may be struck readily under a hand-glass in August and September. It is a native of the Rocky Mountains of South Colorado.

#### ROYAL METEOROLOGICAL SOCIETY.

THE monthly meeting of this Society was held on Wednesday evening, the 15th instant, at the Institution of Civil Engineers, 25, Great George Street, Westminster ; Dr. C. Theodore Williams, President, in the chair. Dr. J. H. Davies, Mr. G. F. Deacon, M.Inst.C.E., Mr. A. S. Helps, and Mr. R. H. Jeffrey, B.A., were elected Fellows of the Society. The following papers were read :—

1. "Report on the Phenological Observations for 1892," by Mr. E. Mawley, F.R.Met.Soc. The Royal Meteorological Society has for a number of years past collected observations on natural periodical phenomena, such as the date of the flowering plants, the arrival, song and nesting of birds, the first appearance of insects, &c. These observa-

tions were supervised and discussed by the Rev. T. A. Preston until 1888, since which time they have been under the direction of Mr. E. Mawley. The year 1892 was on the whole very cold and backward. The frequent frosts and dry weather during the first five months greatly retarded vegetation, and consequently all the early wild flowers were very late in coming into blossom. Bush fruits and Strawberries were, as a rule, good and fairly plentiful. Plums and Pears were almost everywhere a failure, and Apples were considerably under the average. The Wheat crop was a very light one, owing in part to the attacks of blight brought on in many places by the frost in June. Oats, Beans, and Peas were much under the average, while Barley was the chief crop of the year. Potatoes, Turnips, and Mangolds were above the average. During August butterflies were very numerous, the clouded yellow butterfly being exceptionally abundant.

2. "Relation between the Duration of Sunshine, the amount of Cloud, and the height of the Barometer;" by Mr. W. Ellis, F.R.A.S. This was a discussion of the observations made at the Royal Observatory, Greenwich, during the fifteen years 1877-91, from which it appears that in the months from February to October there is, on the whole, a distinct probability of increased sunshine and correspondingly less cloud with increase of barometer reading. The winter in all conditions of the barometer is uniformly dull. Mr. Ellis says that it is evident that high barometer in summer presages increased sunshine, that the effect is less pronounced in early spring and late autumn, and that it becomes slightly reversed in winter.

3. "Winter Temperatures on Mountain Summits," by Mr. W. Piffé Brown. In this paper the author gives the lowest winter temperature on the summit of Y Glyder fach, four miles E.N.E. from Snowdon and 3262 feet above sea level, as recorded by a minimum thermometer during the last twenty-five years. The lowest temperature registered was 9° during the winter 1891-2.

### ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—February 14th. Present: Prof. M. Foster, in the chair; Dr. Masters, Sir J. T. D. Llewelyn, Mr. McLachlan, Rev. W. Wilks, Mr. Michael, Prof. Church, Prof. Oliver, Prof. Farmer, and Rev. G. Henslow, Hon. Sec.

*Soil with Mites, &c.*—Mr. Michael reported upon a sample of earth sent from Jura Forest, and found that it contained wireworms, some Thysanuridae and mites (Gamasidae). The mites were in this case not injurious to plant life, but rather "friends," as they were predatory on other animals. In another sample sent there were Thysanuridae and wireworms, but no mites. The soil being in a bad condition should be treated with gas-lime, or other usual remedies for wireworm. Mr. McLachlan observed on the importance of such investigations as the present, as they revealed what creatures were "friends" to the cultivator, such being very often regarded unwittingly as "foes."

*Turnip Devoured by a Vole.*—Dr. Masters exhibited a specimen from Bagshot, in which the whole of the interior had been consumed, nothing but a thin shell of cortex being left. He also showed a drawing of a monstrous Turnip which had grown not unlike a Mandrake in form.

*Burr Knot on Apple Roots.*—Dr. Masters also showed a specimen from a "Burr Knot" Apple tree, a feature characteristic of certain varieties of Apples, such being used for propagating purposes. It was referred to Prof. Farmer for examination.

*Fog Report.*—Prof. Oliver presented the second report on his investigations upon "The Effects of Urban Fog on Cultivated Plants," which will be printed and circulated for discussion at the next meeting. The following is a brief abstract:—"The report deals especially with the physiological aspect of the question, matters of more purely local interest being reserved for a forthcoming communication. The observed action of fog upon plants is described in detail, and the share taken in this action, by the reduction of light on the one hand and by atmospheric impurities on the other, is critically discussed in the light of the writer's experimental results. The position taken up by the author is that 'fog' is, physiologically speaking, a much more complex affair than has been suspected. In presenting his report, Prof. Oliver explained that the present contribution could only be regarded as a very imperfect statement of the subject, and that he was busily employed in following up some of the more novel lines which he has indicated." Prof. M. Foster moved, and Mr. McLachlan seconded the motion, that the report should be presented to the Council.

*Arum with Two Spathes.*—Dr. Masters exhibited a specimen of this common phenomenon, and remarked that no florist had made any attempt to fix it. The question was raised whether it was desirable to do so, as some thought that two spathes were no improvement to the flower.

*African Produce.*—Messrs. J. Wrench & Sons forwarded samples of leguminous and other seeds raised in S. Africa from English origin. As a general result they had remained constant in character. The Committee expressed their thanks to the exhibitors.

### TRADE CATALOGUES RECEIVED.

Dickson & Robinson, Manchester.—*Agricultural Seeds.*  
Ellwanger & Barry, Mount Hope Nurseries, Rochester, New York, U.S.A.—*Fruit and Ornamental Trees, Roses, &c.*  
Little & Ballantyne, Carlisle.—*Farm Seeds.*  
J. C. Schmidt, Erfurt.—*Agricultural and Garden Seeds.*  
Charles Van Geert, Anvers.—*Fruit, Trees, Shrubs, Roses, Hardy Plants, &c.*

### FRUIT FORCING.

**Vines.**—*Early Forced in Pots.*—The state of the crops depends on the management and the condition of the Vines at the time of starting. Those started last October or early in November, and being strong, well-ripened canes from cut-backs, have, under proper management, the Grapes in an advanced stage for colouring. During this stage the berries swell more than at any other, therefore supply fresh top-dressings of rich material, as turfy loam or lumpy well-decayed manure, with a sprinkling every ten days or a fortnight of dissolved bones three parts, powdered saltpetre two parts, and gypsum one part, by weight, mixed and kept dry. This not only feeds, but encourages root formation, and the new rootlets absorb liquid manure, which should be supplied copiously in a tepid state, and not too strong. Maintain a genial condition of the atmosphere by damping available surfaces two or three times a day, especially at closing time, which should be sufficiently early to run up the temperature to 85° or 90°. The floor may also be sprinkled occasionally in the evening with liquid manure, but not too strong, and the ammonia given off will invigorate the Vines and prove inimical to red spider.

*Stopping, Tying, and Regulating the Shoots.*—In houses that were started a few weeks ago the growths will be in a sufficiently forward state for disbudding, but it should not be attempted before the best breaks can be discerned. The operation should be performed gradually, removing the weakest and worst placed shoots first, and ultimately leaving no more than there is room for the full exposure of the foliage to light, always retaining the most promising for fruit. In very vigorous Vines and under close pruning the weakest shoots often show the best, the others being fruitless, or the bunches are loose and badly set. Then it is best to allow two shoots to a spur, one for growth and to give the next year's crop, and the other for bearing in the current year, these precocious shoots being so enfeebled by the current crop as not to be able to form good buds and well-ripened wood for supplying the succeeding one, and should be cut away after the Grapes are cut, otherwise the spur may be lost and the crop nil. Stopping should take place at one joint beyond the bunch where the space is limited, but two joints should be left where there is room for lateral extension. Tie the growths before they touch the glass, bringing them down carefully, as they are liable to break. Allow sufficient room in the ligatures for the swelling of the shoots, and loosen all those that are too tight.

*Vines in Flower.*—The syringing if practised must now be discontinued, and a comparatively dry atmosphere is desirable during the setting process. Condensation of moisture on the glass should be prevented by a little ventilation constantly, but without causing a draught. The temperature must not be less than 60° to 65° at night and 70° to 75° by day artificially. Shy-setting varieties require careful fertilisation, brushing the bunches lightly with a camel's-hair brush, and then follow with the same charged with pollen collected from such free setters as Black Hamburgs. Muscats should have the bunches well up and with their points to the light, and if they are numerous it is better to remove the surplus bunches before they come into flower than to defer it until the Grapes are set. They should have a night temperature of 65° to 70°, 5° more by day artificially, and 10° to 15° from sun heat. Careful fertilisation is imperative in their case, attending to it on a fine day after the house has been ventilated a short time always when the "caps" part readily from the tips of the flowers, as then the stigmas are ready to receive the pollen.

*Thinning Grapes.*—This work must never be allowed to get into arrears. Free-setting varieties should be thinned as soon as they are fairly out of flower, taking out the smallest berries first and then going over the bunches again, so as to leave only sufficient berries to form a compact bunch, each berry being allowed space to swell to its full extent without wedging or losing its natural form. This requires the exercise of a little judgment, and can only be acquired by experience. Muscats and all shy-setting varieties should not be thinned until the properly fertilised berries can be distinguished, as they may by their taking and retaining the lead in swelling, whilst the unfertilised remain almost stationary in this respect.

*Feeding.*—When the Grapes are set and thinned every encouragement should be given to their swelling, supplying liquid manure in a weak state liberally, always tepid, and surface roots may be accelerated by light mulchings of lumpy manure or turf, kept moist and sprinkled every fortnight or so with a good handful per square yard of the mixture advised for Vines in pots. Even half a pound per square yard may be given where the Vines are weak and carrying heavy crops, and three such dressings are usually enough—one when the Grapes are set, a second when they are about half swelled, and the third just before or when they are colouring. The last dressing will also aid the Vines to plump the buds for producing next year's crop. Maintain a genial condition of the atmosphere by damping available surfaces in the morning, at closing time, and in the evening. Make the most of sun heat by early closing, running up to 85° or 90°, and this will maintain a good temperature into the night, when it should gradually fall to the minimum

figure. Admit air in the morning before the sun has raised the temperature more than 5° to 10°. This should be done without lowering the temperature, and the Vines will be saved from scorching.

**Strawberries in Pots.**—Those ripening should have a rather dry and freely ventilated atmosphere to secure quality and aroma. The temperature for fruits swelling off should be 65° at night, 70° to 75° by day, advancing to 80° or 85° with sun. The second early plants having set well should be reduced to six or eight per plant if fine fruit is desired. When the fruit is fairly swelling the plants may be moved to a house with a temperature of 60° to 65° at night, 70° to 75° by day, with an advance to 85° from sun heat, supplying them with liquid manure copiously, examining the plants once or twice a day, even three times in bright weather, and watering such as require it. Where there are vineries and Peach houses which are started periodically, and Strawberries are grown in pots on shelves near the glass, there will be no need to move them, except to meet special requirements, as they will afford successional supplies of fruit. Introduce more plants as such houses are set to work, also place those in cool houses in the positions they are to occupy for fruiting. If plants are placed in span-roofed frames, half plunged in or stood upon ashes, fruit much finer and a fortnight to three weeks earlier than that in the open ground will be secured, the early and second early varieties producing freely, and are most desirable, especially Noble and Auguste Nicaise.

**Melons.**—The weather has not been unfavourable to forcing operations generally, and the plants are making satisfactory progress, especially those that were transferred to the ridges from the seed pots, the bottom heat being supplied by hot-water pipes in a chamber. In severe weather it is advisable to proceed carefully, as highly heated pipes do considerable injury to the foliage and invite attacks of red spider. A temperature of 60° to 65° at night, 70° to 75° by day, and an advance to 80° or 85° with sun will be suitable, ventilating a little at 75° and close at 85°, rising to 90° or more with plenty of atmospheric moisture. Plants that were shifted into 5 or 6-inch pots should be transferred to the ridges or hillocks, firming the soil well about the balls. Provide a stake to each plant secured to the bottom wire of the trellis; train with a clear stem to the trellis, rubbing off the laterals to that height directly they are discernible, and allow the leading shoots to extend two-thirds up the trellis before stopping. If the plants are short-jointed rub off every alternate lateral on the opposite sides of the principal shoots. Under favourable conditions the laterals will show fruit at the second or third joint, otherwise stop them at the second joint. Keep the bottom heat steady at 80°. Water carefully, and always at a little distance from the stem. A genial condition of the atmosphere should be maintained by damping in the morning and afternoon, also before dark if the surfaces become dry.

**Cucumbers.**—Plants raised from seed sown at the new year, and transferred from the small pots to the ridges or hillocks in the Cucumber house, need not be stopped until they have extended two-thirds up the trellis. Train the laterals about 1 foot distance apart, and do not stop them until they have extended about two-thirds across their allotted spacesideways. A vigorous growth is thus secured, and the plants will crop much better and longer than those which are pinched from near the bottom of the trellis with a view to early fruit. If the latter practice is followed, care must be taken not to overcrop the plants, or the growth will be started, and not enough made for successional bearing; upon which depends a regular supply of fruit. If the plants have been shifted into larger pots, and not yet turned out into the fruiting bed, it should be done before they become cramped at the roots.

**Winter Fruiters.**—The plants that have been in bearing will be much benefited by removing some of the surface soil, and supplying fresh lumpy loam, sprinkling a handful of superphosphate of lime over each square yard. Now the light and sun heat tell advantageously and the plants feel their influence, a greater supply of atmospheric moisture is needed. Maintain a night temperature of 65°, allowing 5° more when the external air is mild, and 5° less in the morning when the weather is severe, 70° to 75° by day artificially, and keep through the day at 80° to 85° or 90° from sun heat, always securing a good heat in the afternoon by early closing, and if the temperature rise to 95° or 100° it will benefit the plants. Enough ventilation in the early part of fine days should be given to insure a change of air, avoiding cold currents. Liquid manure once or twice a week will be required by plants coming into bearing. Thin the fruits well, remove superfluous growths, bad leaves, tendrils, and male blossoms, stopping the shoots one joint beyond the fruit, and in no case permit crowding or overcropping.

The plants in pits and frames are moving now the weather has become more favourable, but the foliage is tender, therefore ventilate carefully, avoiding currents of cold air, placing a thin mat or some hexagon netting over the openings so as to break the force of cutting winds. Cover the lights with double mats at night, and attend to the linings regularly, renewing the old linings as required. Prepare material for fresh beds. Two parts Oak or Beech leaves, and one part stable litter, make the best beds at this time of the year. These should be thoroughly incorporated and thrown into a heap about a fortnight before it is desired to make the beds. In a few days it will be seen whether there is sufficient moisture to produce decomposition, to which fermentation or heat is due; if not, turn the whole, sprinkling with water so as to moisten the mass. When in good heat turn again outside to inside, blending the whole well, two or three turnings being required at intervals of four days to sweeten the material—and allow the rankness to pass off. The bottom heat of fermenting beds should be 85° to 90°.

## THE KITCHEN GARDEN.

**Celery.**—A firstsowing of Celery ought now to be made. One of the dwarf early white varieties, Veitch's Early Rose being a good companion for these, would be the best for ordinary purposes; but if for early exhibition a taller variety, such for instance as Wright's Giant White, is preferable. Sow the seed rather thinly in pans, place on a hotbed or in rather brisk heat, cover with a square of glass, shade heavily and keep uniformly moist till germination takes place, after which gradually expose to daylight and transfer to a shelf still in moderately strong heat. Early Celery does not always germinate so well as is desirable, therefore sow the seed rather freely though not thickly, and if the first sowing fails make a second sowing at once.

**Cauliflowers.**—Small plants wintered in cold frames would be more readily planted if first established in small pots. Placed singly in 3 inch or slightly larger pots, good loamy soil being used, and set for a few weeks on a warm greenhouse shelf or in a slightly heated pit, they would develop into strong well rooted plants that would move into handlights and other sheltered quarters without experiencing much of a check. Any plants raised early this year should be also potted in preference to pricking in boxes, as they cannot often be moved out of the latter with a good ball of soil about the roots. A light position in gentle heat is the best place for these young plants and also for pans containing newly sown seed. If there is a poor stock of autumn raised plants of Dwarf Erfurt, Early London, or other favourite second early forms, sow seed in pans or boxes at once. Also raise early plants of Autumn Giant, which if properly treated will commence hearting in late in August. Should a good stock of Early Forcing or Dean's Snowball have been raised, put out the surplus plants or those not required for growing under glass, either in rough frames at the foot of south walls or on warm borders, before they become badly root-bound, and protect with mats.

**Onions.**—It is yet too early to sow seed in the open, but if extra fine exhibition bulbs are required plants must be raised under glass. Ailsa Craig, Anglo-White Spanish, Sandy Prize, Improved Wroxton, and Rousham Park Hero are all more or less popular with exhibitors; and seed being rather dear, sowing in heat is also the most economical plan. If the seed is sown thinly in pans, or better still large shallow boxes, the plants can eventually be transferred direct from these to the open ground. A vinery being forced, or other moderately warm forcing house, is suitable for raising Onions, the plants being raised well up to the light before they become drawn and weakly.

**Leeks.**—If these are also wanted extra strong and early for exhibition purposes, seed of The Lyon, Dobbie's Champion, Prizetaker, or any other large-growing variety should be sown at once in heat, the plants to be treated very similarly to early Celery.

**Carrots.**—Unless there is an extra demand for tender young Carrots, two good sowings under glass will generally meet the case, successional supplies being had from a warm border. In very many instances no glazed lights can be spared for early Carrot culture, and in all such cases it is a good plan to form a hotbed in a sheltered position, surmounting this either by a rough frame or with boards held together by means of outside stakes driven well into the manure. About 6 inches of fine sandy soil should be placed on the manure, and the Carrot seed be then sown either in shallow drills 8 inches apart or thinly broadcast, and covered with a little sifted soil. If the variety Nantes Horn is selected, a single bed will yield numerous bunches of early and very tender roots by way of thinnings, those reserved being left till the roots are large enough for the July or early August shows. Roots thus grown are particularly well formed and have clear skins.

**Early Radishes.**—These may always be sown either in drills midway between the rows of Carrots or thinly broadcast. They will be fit for use some time before all the space is needed by the Carrots. Supposing these beds are formed and the seed sown late in February or early in March, temporary protection in the shape of a rough framework supporting mats or old carpeting will be needed, though in some cases strong stakes about 4 feet high are used for the double purpose, keeping the boards together and supporting a covering of trebled fish nets, all the protection afforded. If desired, such heaps of manure and soil may be utilised for growing Vegetable Marrows during the summer.

**Early Turnips.**—Frosts have destroyed nearly or quite all the roots left in the open, and the stock under cover is far from being enough in most cases, to carry on the supply till young Turnips are available from the open borders. This being so those who have the convenience ought to grow some under glass. Anything like hard forcing is out of the question, but the Extra Early Milan can be forwarded very considerably in a frame on a gentle hotbed. The frame after being set on the bed should be about half filled with some of the shortest of the heating material, on this being placed 6 inches of good loamy soil. Make the latter somewhat firm; sow the seed thinly and broadcast, and cover with fine soil. Either cover with glazed lights and mats during nights, or with the latter only. In the former case ventilate rather freely after the plants are up, giving abundance of air during warm weather, and thin early where at all crowded. If the plants are left about 4 inches apart the thinning-out can be done according as the roots attain a serviceable size.

## PLANT HOUSES.

**Alocasias.**—Plants that need more room should be repotted at once. Work old decomposed material carefully from amongst the roots, which is best done by washing it out in tepid water. The plants should be allowed to drain thoroughly before they are again placed into pots.

If the stem of the plants have become lengthy the lower portion may be cut away. Liberally drain the pots or pans and put the plants in the pots, so that when the surface is mossed the lower leaves just rise out of it. These plants grow well in a compost of peat in lumps, fair sized pieces of charcoal, and living sphagnum moss. For strong growing kinds fibrous loam may be used with the peat. When this is employed some coarse sand should also be added to the compost. After potting place the plants where they can enjoy a close moist heat. If a gentle bottom heat can be given them all the better. Syringe freely, but water carefully until the plants commence rooting freely.

**Anthurium crystallinum.**—Plants of this kind may also be repotted. Young plants that have the compost in a sweet condition about their roots may be placed into larger pots; and others that have decayed material about them should have it removed, and be treated as advised for *Alocasias*.

**Anthurium Andreanum.**—Established plants that need repotting as well as young plants, may be treated the same as advised above. Plants that have grown tall should be cut close back, when they will break freely from the base, and make excellent bushy plants in the course of a season. When once cut-back plants have fairly broken into growth the old material may be removed from the roots, and the plants placed into smaller pots. The stem can be cut into lengths of two or three joints, and the pieces placed singly in sand and sphagnum moss into 3-inch pots. The portions of stems put into brisk heat in the propagating frame will soon form roots, and by the winter will make excellent plants for flowering on the side stages of the stove.

**Anthurium Schertzerianum.**—Specimens that have been resting in a temperature of 50° may be introduced into the stove, when they will quickly commence to push up their flower spathes. Those kept in the stove will be very much benefited by being rested for a time in a lower temperature. While under this treatment give the plants less water. Water those carefully at first that are introduced into the stove. All plants that have commenced root activity may be top-dressed or repotted. These plants do not need much material about their roots. They require an open compost, and abundance of water when growing. This variety is not very particular about soil; we find the plants succeed well in ordinary moss and crocks, also in lumps of peat, charcoal and moss, and equally well in fibrous loam, moss, crocks and charcoal. Fine soil should not be used, for very rarely do the plants succeed in it. They grow rapidly when supplied with fresh healthy material about their roots.

**Nepenthes.**—Plants that need repotting, or placing in larger baskets, should have immediate attention. If grown in pots, turn them out and place the plants into those of a larger size without disturbing the roots. If in baskets, the old baskets should be placed inside others, and the latter filled with fibrous peat and charcoal, with a good layer of living sphagnum moss round the sides and on the surface. These plants do well in loam, sand, and charcoal, with moss on the surface; or they may be successfully grown in a mixture of peat, sand, and living sphagnum in equal proportions. Plants that have grown cut back, but do not disturb their roots until they have commenced new growth. Portions of the stem may be inserted in small pots with the leaves attached, and placed in a brisk heat in a propagating frame. Shoots on established plants that have made four or five leaves may be pinched; this not only keeps the plants dwarf, but induces them to branch and produce pitchers freely.

## THE BEE-KEEPER.

### APIARIAN NOTES.

OWING to the temperature of February being lower than it was in January bees have not been much abroad. Occasionally during sunshine a few venture out scanning the flowers, but soon return to their hives. With one exception mine have not yet had a thorough flight, but as all are healthy I have no anxiety for them. With Heaths, Crocuses, Snowdrops, Hepaticas, Arabis, Hellebores, Aconites, and other flowers there will be inducement to the bees to work when the temperature becomes a little higher. A watch will be kept over their movements, and if there is the slightest suspicion of effete queens they will be examined so as to ascertain their true condition, and disposed of accordingly.

#### ENTRANCES.

These will be kept at their winter's width, especially during the night, until the bees show signs of being dissatisfied or oppressed, when they will be widened a little as circumstances demand. My hives are all dry, and will not be interfered with, but there may be some who have their bees in hives not similarly arranged or constructed that are damp. Such hives should be overhauled on the first opportunity, quilts dried, and the frames with the bees transferred to a clean, dry, and slightly heated hive. Those short of stores should be fed as early as convenient with not less than 6 lbs. of the best cane sugar, then left alone.

#### LEGISLATION FOR FOUL BROOD.

It appears that Messrs. Cowan and Carr are still agitating for assistance from Government for suppressing foul brood in hives.

They cannot be complimented on their success if they can only effect this object by the clumsy and expensive method of destroying the implements necessary for honey gathering. It is to be hoped that Government will not accede to their unnecessary demands, especially as foul brood can be easily cured without such drastic modes as destruction. However, if it could be made illegal to allow untenanted foul-broody hives to stand in any apiary much good would be done.

No doubt it would please the King William Street *savants* if they could have the nomination for appointment of inspectors, but there are matters of grave importance to be considered in this reference. Instead of inspectors subduing foul brood they would be just as likely to be the means of spreading it, while they would certainly be the direct cause of much conflict. I am not a law-breaker, but if such an act were passed I would do all in my power to resist its application. I should resent any interference whatever with my hives by an inspector, who might have the germs of infection about him from the apiary of his last inspection.

I never open my hives after October until they have swarmed, and I would disallow any stranger to do so either who may have no more knowledge than I possess myself. Nor would I allow anyone to injure my bees or their brood with smoke. Common sense has taught me how to have an immunity from foul brood amongst my hives for more than thirty years, and I trust Parliament will reject any attempt to foist upon the public measures at once arbitrary, unjust, and unreasonable at the expense of the taxpayer.

#### WINTER COVERINGS.

I recently commented upon several absurd ideas advanced by some American apiarians. I now quote one more sensible. Mr. A. E. Manum, in *Gleanings* for February 1st, says, after covers are removed he "places over the frames some kind of quilts, and over these 6 or 8 inches of some kind of absorbent, such as dry wood shavings." He also explains the advantages of such coverings in an intelligent way—just the same methods that have been repeatedly advised in the pages of the *Cottage Gardener* and *Journal of Horticulture* for upwards of thirty years.—A LANARKSHIRE BEE-KEEPER.

## TO CORRESPONDENTS

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Chrysanthemums** (J. W.).—We have received the two blooms, if blooms they can be called, of *Etoile de Lyon*. No doubt larger and fresher examples would be useful for decorative purposes, and probably the small ones you posted did not arrive in the condition you expected they would. They were so crushed as to be useless.

**Heating a Greenhouse** (Heater).—The question of boiler is very much a question of fuel. With coke mainly a coil or conical boiler would answer; with coal mainly you would perhaps find a saddle boiler the most suitable. Either kind rightly set and the pipes properly arranged would, with appropriate fuel, answer your purpose admirably. The prices of boilers are given in the lists of vendors.

**Peach Buds and Paint** (E. S.).—Keeping a house close for some time immediately after painting the woodwork would have a deleterious effect on the buds of Peach trees, and we are not surprised to hear that many of them are turning brown and falling prematurely. If provision is made for heating the house, fire ought to have been employed for excluding frost from the plants with constant ventilation.

**Sheltering Screens** (A. H. E.).—If the enclosure is small, and a medium-sized hedge is only needed, and not at the same time a fence against cattle, the Evergreen Privet would answer your purpose, and it grows quickly in good soil; as a barrier and shelter combined a good Thorn or Quickset hedge is the best. If the enclosure is large, and you desire tall screens as quickly as possible, you may do as Mr. Cannell did at Swanley—plant hedges of the Lombardy Poplar, and trim them as desired with pruning shears.

**Moss on Lawn (Ipswich).**—As the soil is of a somewhat clayey nature, it would be much benefited by a dressing of lime applied in a freshly slaked state; it would destroy the moss and improve the soil, though it may brown the grass more or less. Little browning, however, would occur if the lime was slaked off the ground, and when cool distributed evenly by hand at the rate of a peck per square rod, the lime having been passed through a sieve with  $\frac{1}{4}$ -inch mesh to rid it of stones. Air-slaked lime, that is, freshly burned lime, placed in a shed so that air can act upon it freely, and when fallen to a powder may be used as before advised. Another plan is to take equal parts of air-slaked or freshly slaked lime, wood ashes from twigs as hedge clipping or "drawings" of brick ovens, and soot, all perfectly dry, mix, and apply at the rate of a peck per rod. This is one of the best manures for lawns, and equally good against moss and worms. It is best applied early in spring, say February or March. Lawn sand is used to destroy Daisies and other weeds. It must be applied in strict accordance with the instructions; it generally browns the grass, but this soon recovers and grows vigorously afterwards.

**Carnations Dying (Mrs. Savory).**—We are sorry for the misfortune that has befallen your plants. As you say the specimen sent is one of the best we are obliged to advise you to burn every one of them. They are devoured by a fungus (*Helminthosporium*), and every vestige should be burnt for destroying all the spores possible. It is stated in the "Carnation Manual" (Cassell & Co.) that Mr. Charles Blick, gardener to Martin Smith, Esq., banished the fungus by persistently sponging the plants with a weak solution of Gishurst compound, but this would be long before the attack was so deeply rooted as in your plants. Sulphur has no effect in destroying the fungus, but precipitated carbonate of copper and ammonia solution might prove a deterrent, as it is against fungus on Tomatoes. We are not aware that precipitated copper carbonate is kept in stock by chemists, and it is best to manufacture it at home. Procure 3 lbs. of copper sulphate, and dissolve it in hot water in a tub. In another vessel dissolve  $3\frac{1}{2}$  lbs. of washing soda in hot water. When cool pour the soda solution slowly into the copper solution, then add water until the tub is full. Stir the solution thoroughly and let it stand twenty-four hours, then syphon off the clear liquid and add fresh water. Stir again and allow the solution to stand twenty-four hours, syphon off the clear liquid as before, then remove and dry the sediment, which is carbonate of copper. The half of a petroleum cask answers very well for precipitating the copper, and a syphon is easily formed of half-inch garden hose. There will be 1 to  $1\frac{1}{2}$  lb. of copper carbonate. The liquid ammonia, strength 26°, may be procured of any chemist. Where there is little use for an instrument to apply fungicides and insecticides a syringe specially made for spraying answers very well. As a syringe "Stott's" is efficient for spraying. A close damp atmosphere favours the growth of the fungus.

**Pruning "Maiden" Trees (J. B.).**—Maiden trees of one season's growth have only one stem. For forming bushes this should be cut down to within a foot from the ground, and three or four branches encouraged equi-distant, and as nearly uniform in strength as possible. In the autumn, after the leaves fall, these branches should be cut back to about a foot, and the tree will then form sufficient branches for a good foundation and a free open bush for bearing. These main branches should be more, rather than less, than a foot apart, and the tips of the branches only shortened in the interest of symmetry and uniformity. The side growths issuing from these main branches may be shortened in summer—say in June—to six good leaves, and any further growths pinched to one leaf, these summer-pruned shoots to be cut back to about an inch of the base in winter. When the branches of trees are very wide apart, and the summer growths not so strong as to crowd the trees, early summer pruning is not required. Some of the most fruitful trees we know have the main branches 2 feet asunder. They have never been shortened, except about twice after planting; and they are only pruned once a year—in the autumn. The heavy crops of fruit keep the growth in subjection. These are not pigmy trees, but large and very real fruit producers. Naturally formed bush trees are the easiest of all to manage, and if the growth is too exuberant in the third year it is an excellent plan to carefully dig up and replant the trees. The simple method of forming ordinary open bush trees applies to all kinds, but Pears, Plums, and Cherries are often grown as pyramids, and then a central leader must be secured to a stake, and side branches at the same time encouraged, not less than a foot apart, and the lower ones longer than those above them. You have done right in planting "high" in your strong soil, and in a few years replanting will probably be found highly advantageous in fruit production. If fruit buds form at the extreme ends of branches, those ends must be cut back to the smaller growth buds if further extension is desired. "Seedling Apple" stocks are "free" stocks, and in growth more resemble the character of the Crab than the more precocious Paradise stock. They will probably answer in your soil, especially if the trees are replanted, should undue luxuriance render this desirable in the course of two to four years. The chief desiderata in fruit culture are surface roots, firm yet stout wood, the branches so thinly disposed that the sun can shine between them right through the trees, and cleanliness. Secure these essentials and you will have plenty of blossom buds, to be followed by crops of fruit, birds and weather permitting.

**Stock for Plums (N. E.).**—The Damson, White Pear Plum, St. Julien, and Mussel stocks are all used for Plums. Damson and White Pear Plum may be termed dwarfing stocks, and as such only suitable for garden trees—half-standards, bushes, pyramids, cordons, espaliers, and strong-growing varieties which it is desirable to dwarf.

Except in free, rich soils, neither is good for the very prolific kinds of Plums as standards on grass, they simply bearing themselves to death. St. Julien is, perhaps, the best stock for the Early Rivers, as well as others (where the ground is kept bare, as in market gardens, and the soil is rather strong and not deeply cultivated), on account of its fibrous root formation. For standards, especially for orchards in grass, the Mussel stock answers well, and that we advise for your purpose. The Sloe stocks, so-called, are very little used by nurserymen. The Blackthorn or Sloe (*Prunus spinosa*) makes a dwarfing stock very liable to push infinite suckers; the Bullace (*P. instititia*) forms a better stock for dwarfing purposes, yet it throws up suckers much more freely than the common or wild Plum (*P. domestica*), all merely sub-species of *Prunus communis*, which is found wild here and there throughout Europe and North Africa. The Sloe, however, is confined to Europe, but the Bullace, according to Hooker, extends to North Africa and the Himalaya. It would be better to procure some Mussel stocks, as no reliance can be placed on the Blackthorn. The large, round, red Plum, which comes into use with Rivers' Prolific, or soon after, may be Early Orleans. It is a favourite in the London markets, but the tree is not a great cropper, and requires a warm strong soil. A far more profitable Plum is the Czar, which is nearly as early as Rivers' Prolific, round, purplish red, and carries a fine bloom. The tree is a very free grower, of upright habit, and produces its fruit in clusters profusely. Sultan may be termed an improved Prince of Wales, the tree being, unlike that variety, a free grower, and not liable to collapse suddenly when it gains a good size. Goliath is also a purplish red Plum, second early, and a heavy cropper; but it is addicted to dying suddenly, like Prince of Wales, when the tree becomes of profitable size. Emperor is later, has roundish-oval, large, Orleans-like fruit, the tree being vigorous, and produces fruit abundant. This is an old variety, known in North Wales as Denbigh, where it succeeds admirably, but is known as Cox's Emperor generally. Rivers' Monarch is a valuable late Plum that will force itself into popularity.

**Names of Plants (G. E.).**—1, *Ornithogalum nutans*. 2, Specimen damaged, kindly send another and give particulars as to the habit of the plant. (E. S.).—*Dendrobium speciosum*, probably var. Hilli.

### SPRING CROPPING.

EVERY farmer having a full supply of Thousand-headed Kale now will agree with us that it is a crop worthy of a prominent place both in spring and summer cropping. Even those without any must admit the high value and great usefulness of it for every reason that a practical man can have for the cultivation of his most cherished crops. It is for such men especially that we are now writing, to give them a timely reminder of the un wisdom of neglecting a means of obtaining an abundant supply of nutritious green food at midwinter; of relieving the run upon hayricks; of imparting freshness to the milk yield; of supplying the ewe flock with a safe substitute for roots before, during, and after the lambing season. It grows under high cultivation upwards of a yard in height, the stems are thickly set with side shoots, and it is so wholesome that sheep folded upon it during winter and spring show no tendency to scour. An acre of it affords enough food to sustain a hundred sheep for a month, or much longer if they have dry trough food as well. It is quite hardy, and is simply invaluable this winter with hay rising in price almost weekly; yet it is only occasionally to be met with. In our frequent long journeys it is only very occasionally that we see it being turned to full account; yet there can be no more reason for neglecting it than there is for not having a full supply of, say, Lucerne, or any other of our best fodder crops.

Under good management it is quite possible to have plenty of Thousand-headed Kale all the year round; but the fact of its being so hardy renders it most valuable when other crops cannot be had. For use in the last three months of the year it is drilled in April and May, or if sown in seed beds for transplanting then make sowings in March and April to transplant in June and July. For spring and early summer use drill the seed in July and August. There are advantages as well as disadvantages in either of these methods of culture. By sowing in seed beds 2 lbs. of seed affords sufficient plants for an acre, with an ample surplus for failures. The plants are kept under close observation during the critical early stages of growth, and are easily protected from insects; but they involve the additional cost and risk of transplantation. By drilling the cost of transplanting is practically avoided, though it may be found necessary to transplant some to fill vacancies. The checked growth, so unavoidable in transplanting, is avoided; yet about three times the quantity of seed is required, and the young plants are exposed to attacks of insect pests which may destroy the whole of them.

In some soils, more particularly those which are light and sandy, club-root may affect the crop so seriously as to spoil it. To combat this use heavy dressings of farmyard manure, transplant large vigorous plants, which, whether purchased or home-raised, must have the stems examined, all maggot swellings cut off, and the roots dipped in a puddle of clay, soot, and lime, moistened and brought to the proper consistency with strong soapsuds and petroleum, first mixed by pouring a wineglassful of petroleum into a gallon of hot soapsuds. If there is any reason to fear attacks of this pest among drilled plants, a liberal dressing of chemical manures (always beneficial), would do much good in promoting vigorous growth from the seed germination. In any case these soluble salts are desirable, both for vigorous growth of the young plants, and for bulk of crop.

Plant or thin to 30 inches apart, so that the horse-hoe may be used freely among the plants, and when the crop is transplanted, the hoe can be used both along and across the field, as the plants stand in true line both ways. This is easily

managed by reversing the hoes of a steerage or horse-hoe, setting them 30 inches apart, marking the land first one way, and then crossing the other way, each plant being placed where the lines intersect. Accuracy and dispatch are thus insured, and the planting is done with marvellous celerity; often with much needless roughness and exposure of plants, which we have seen shot out of carts in heaps on bright hot days, to be dropped singly by boys for the planters. The severe check thus given to the plants might be avoided, though we must admit that they recover from it and grow freely enough to produce a useful crop.

The first drillings may follow sheep folds on Rye or late Swedes; the former, preferably, because Swede folds answer so well as a preparation for spring corn. Summer drillings follow Winter Oats conveniently if the land is clean, chemical manures only being used liberally, as there is no time for carting farmyard manure then. A surface dressing of nitrate of soda now promotes vigorous growth in the summer-sown plant.

### WORK ON THE HOME FARM.

The time has come for top-dressings of chemical manures to be given to permanent pasture, mixed seeds of Grasses and Clovers, Vetches and Oats, and winter corn. First comes the grass and other fodder crops intended for hay or silage, all which we like to have the manure on by the end of February. Never have we had better results than those from using  $\frac{1}{2}$  cwt. nitrate of potash,  $\frac{3}{4}$  cwt. nitrate of soda,  $\frac{1}{2}$  cwt. mineral superphosphate, and  $\frac{1}{2}$  cwt. steamed bone flour, or  $2\frac{1}{4}$  cwt. per acre of the best possible combination of nitrogenous and mineral manures. It was solely owing to its high price that we ceased using nitrate of potash, taking the muriate as a substitute. It is by using such a mixture yearly that we have sustained fertility in the soil wherein these important crops grow. Avoid using nitrate of soda alone on permanent pasture; use it there always in combination with the other manures we mention.

To both winter Oats and Wheat a top-dressing of nitrate of soda may be given to good purpose in March. One or even two hundredweight per acre where mineral manures were used when the corn was sown, induces growth of remarkable vigour, and a corn yield altogether above the average. In good mixed soil it is still entirely possible to grow Wheat profitably by the use of reliable seed, good manure, and early sowing. From four to eight hundredweight of soot per acre may also now be used as a top-dressing both for corn and fodder crops. The manurial matter in soot is sulphate of ammonia; it may be used advantageously on permanent pasture where mineral food is known to be present in sufficient quantity, but where soil is deficient in mineral food, then basic slag or superphosphate should be used with the soot. Avoid mysterious compounds of soot under fanciful designations. Soot cannot be regarded as a complete manure, because it is only carbon in combination with sulphate of ammonia.

More caution is exercised in using nitrate of soda for Barley than for any other crop, because it is so liable to prove hurtful to quality. It has been laid down by an able chemist that three-quarters cwt. of nitrate of soda per acre is the maximum quantity as a top-dressing for Barley. For Oats it may be used much more freely with advantage, also for mixed fodder crops, to which the scarcity and high price of hay during this and the two preceding winters should induce special attention. The best meadow hay in Leicestershire now costs about £6 per ton.

### REMARKS.

- 12th.—Alternate cloud and sunshine till 3 P.M.; wet from 4 P.M. to 5.30 P.M.; fine night.  
 13th.—Drizzly early; overcast morning; frequent sunshine in afternoon; rainy or drizzly from 5.30 P.M.  
 14th.—Dull, drizzly, and mild morning; gleams of sun at 3.30 P.M.; wet from 4 P.M. to 5 P.M.; fair night.  
 15th.—Overcast and slightly foggy, with occasional drizzle, and heavy rain from 1 to 1.30 P.M.  
 16th.—Overcast with occasional drizzle in morning; generally sunny after 1 P.M.; a little drizzle at 5.45 P.M.  
 17th.—Sunny morning; generally cloudy in afternoon; rainy evening.  
 18th.—Overcast early; sunny at times after 11 A.M.; spots of rain in evening.  
 Another rather mild week, with frequent slight rain, but no heavy fall.—G. J. SYMONS.

IT is well from time to time to note the position in which we stand and the prospects in that which interests us most ; and as this, with us, and all of kindred tastes, is horticulture, we would fain see if this still holds its own in this our land of gardens. What better time for this than when Nature is awaking from its rest of winter under the influence of the sun, which, as Mr. Richard de Gallienne has said,

“ Comes to meet us with his big warm hands.”

But this is not so everywhere, at least just at present. The glow of a joyous day which

“ Makes the birds sing  
And brings the buds again ”

is all too quickly followed by southern rains and northern snows ; but yet we look hopefully on. The snows will melt away and the floods depart, leaving the earth the richer, and the flowers and fruit will come to cheer us in due course.

What is horticulture ? Garden culture, literally—making the earth bring forth its riches by the art of man. Riches ? Is not the very word a mockery to those whose land has failed to yield the hoped-for increase ? If it is, why should this be so ? Look around, and the reason will reveal itself. Are we, as a nation of cultivators, doing justice to the land ? Are we doing all that can be done in the rivalry of the world to keep ahead of our competitors ? In horticulture, broadly speaking, we are ; in agriculture the case is doubtful. What is the test ? There is no better test than is afforded by the energy that is displayed in, and the character that is stamped on, our public exhibitions, both in London and the provinces. If the number of horticultural shows decided upon and proposed may be considered as indicating the general condition of horticulture in this country, then may it be considered as in an active, if not a flourishing, state.

There is not a doubt that the public interest in gardening is greater than ever it was before, and it is undeniable that at no period in history were there anything like the number of individuals sharing, some pleasurably, some profitably, some perhaps disappointingly, in horticultural pursuits, for there are various grades of workers. The good influences that gardens exert is universally admitted, and hence the efforts that are made for the acquisition of open spaces near towns, which by the gardener's art may be converted into beautiful places of resort for the populations ; hence also the movement, which is gathering strength yearly, for the provision of gardens and allotments for all who may be able to make their lives brighter and better by their acquisition. And hence, again, the enormously increased number of exhibitions for affording opportunities for the display of flowers, fruit, and vegetables in the best form in which they can be represented by cultivators. All this denotes activity, and it is pleasing to observe the enthusiasm that exists in this direction. Nothing great or good has been achieved without enthusiasm when tempered with sober judgment and prudent action. There is plenty of enthusiasm now in the gardening ranks, and also, it may be added, plenty

of shows in store. In London there may be said to be a piling up of them looming in the distance, and not a few of those persons who are in a position to support those shows and make them successful from a spectacular point of view, are beginning to doubt the prudence of an undue multiplication of the number to which they are expected to contribute.

The meetings of the Royal Horticultural Society and the special exhibitions in association come fortnightly ; then there are the two great general Shows of the Society. Added to these we have the established shows of the Royal Botanic Society and Crystal Palace, also the announcement of fortnightly Shows at Earl's Court during the season ; and before these terminate the National Chrysanthemum Society steps in to give a foretaste of the brightness to follow in the autumn. It is to the crushing and crowding of summer shows, however, that is being regarded with some anxiety by persons who are expected to share in making them worthy of the name and nation. Still, though difficulties may be experienced in finding time and products for exhibition, these usually appear to be overcome when the moment arrives for action by those who desire to have their specialities represented in public. It is wonderful to see the magnitude of the resources of enterprising horticulturists as represented at the many shows both in London and the provinces. Is there a nation in the world able to provide so many and such large and varied horticultural displays over such a long period as our own country ? And is there any country in which higher cultivation is displayed in so many aspects and with so many products—plants, flowers, fruits, and vegetables—as our own ? Notwithstanding our shortcomings, we very much doubt if there is ; and if there is, let the facts be known that sustain the proposition ; then if we are behind we must make another effort.

The love of gardening is growing amongst us. The spirit of endeavour is more than ever animating our populations to do better than has been done before. Is the nation aroused to the need and the duty of strenuous effort towards excellence in production ? If so, then will the wave of depression that so many feel is passing over us be a blessing in disguise. We utterly and absolutely decline to believe that we are destined to be left behind in the race for supremacy. Difficulties have been the opportunities of our race, as many a struggle by land and sea have shown ; then why, if the inherent spirit of perseverance has enabled us to triumph in the dire necessity of destructiveness, why should not that same spirit, wisely guided, carry us on to the goal of success in the altogether more ennobling, though not equally appreciated, work of productiveness ?

If every man would strive unceasingly to do the best that the best have done, then would a revolution be effected in the development of our resources — then would plenty, humanly speaking, supplant the poverty that many who are worthy have to endure—then would confidence be established and prosperity be restored, and the cloud that many feel rests heavily over our land eventually be removed.

A wholesome sign to a better and a brighter future is foreshadowed in the hold that horticulture is gaining on the people. Its force of attractiveness is recognised by those who are alert in bringing it into prominence for arresting the attention of the millions, and drawing them to the centres where they are sought to be. For this we are glad. We want to see the art made prominent and the greatest possible number take pleasure in it, because then will follow practice, and in this we hope to guide. In what way ? Look around, scan diligently, examine closely, weigh carefully all that is said by some of the masters of the art of gardening in the *Journal of Horticulture*, for there we are impelled to believe, having faith in those who teach what they know to be true, that safe guidance may be found by those who seek knowledge in its pages.

## VINES AND VINE STOCKS.

MUCH matter that must have been interesting and instructive to practical men has recently appeared in your columns regarding the results of grafting certain varieties of Grapes on various stocks. To me the subject was very interesting, because for many years I have been experimenting in this matter. Perhaps, therefore, a few facts that have cropped up in my practice may be of interest to your able correspondents, as their experience and suggestions have been to me. I may in the first place say that I have come to the conclusion that, in course of time, the stock ceases to have any, or next to no influence, either for good or evil, on the scion unless a proportion of the stock be allowed to develop stem and leaves as well as the scion, and that if the development of the stock be rather more than that of the scion, the more pronounced will be the alteration produced.

About thirty years since I planted two Vines of Gros Guillaume at the warmest end of mid-season Black Hamburg vinery. The bunches produced by these were larger and looser than I care to see in any Grape. The colour, too, was not satisfactory. A branch of this variety was attached to one of the Black Hamburgs. The transformation was very marked in the more compact bunches, increased size of berry and jet blackness of colour, easily discernible on entering the vinery. One of the experts who saw them and said of them, "What fine Hamburgs" was the late Mr. Henderson, then gardener at Trentham. This Grape on the Hamburg was also much more fruitful than on its own roots when pruned closely.

In order not to unnecessarily burden your columns with a tedious story, I will pass over a variety of experiments and refer to some of more recent years. On entering on the charge of these gardens, which, as you know, are situated in a very wet, sunless climate, and in a most unfavourable situation—low, flat, and very damp—I experienced the greatest difficulty, not in growing Muscat of Alexandria Vines of great strength, nor in producing fine bunches that set well and went on satisfactorily up to a certain stage, but never finished, as I had been accustomed to produce this Grape in a drier climate, and with much more sunshine. At a certain stage the functions of the Vine ceased to a great extent and the foliage gave way prematurely. The border nor drainage could not be saddled with the defect. After battling without satisfactory improvement for many years, grafting on various stocks was resorted to. The stocks being chiefly Black Hamburg, Lady Downe's, and Gros Colman. It came out distinctly that some amelioration of the evil took place where no growth was allowed from the stocks except the scion. A marked improvement was gained only when a good proportion of the stock was allowed to grow as well as the scion. This result led to the inarching of Muscats on, in the first instance, Black Hamburgs, where two bearing rods were allowed to one of the Muscat. The produce from these Vines has been very satisfactory, although in the point of temperature I had to make a compromise. The Muscat rods have continued for eight years to produce very fine bunches, have set exceptionally well, and retained their foliage in good order to the last, and finished the fruit very well indeed. In another house devoted chiefly to Gros Colman and a few Muscats, a Muscat rod has been attached to a Colman with two rods, and the difference in the produce has been very marked in the case of the Muscats. This latter is a better arrangement, as the Colman rejoices in a high temperature, and also requires it for a long season to make it worth growing as far as flavour is concerned.

These two cases led me in 1891 to work several Muscats on a strong, healthy Gros Colman in another house, and the Muscats produced on these grafts last year were remarked by all who watched them to be a great improvement to any previously grown in this house on their own roots. In this case the Muscat grafts are put on half-way up the roof, and so the bottom half of the canes are Gros Colman, and the upper half Muscats. This season will develop the experiment more fully, though judging from some very weakly "shows" that under ordinary circumstances would not have been left, I have no doubt as to the results. Such tiny bunches set very well, and developed into compact bunches of large and well-finished berries. This is the house in which I tried all other remedies I could think of unsuccessfully, while the Muscats were on its own bottom. Raisin de Calabria, managed in this way as a stock, has also produced much-improved Muscats, and I have no doubt that any hardy strong-growing stock would greatly improve them under similar conditions. Such hardy Vines in an indifferent climate retain their foliage later in the season than Muscats on their own roots do, and I have proved beyond any doubt that the limb of Muscat attached shares in the correspondingly extended season of root activity.

One of your correspondents has lately related how he found Gros Colman much improved in flavour when grafted on the

Muscat. I do not say that his deduction is incorrect, but may the improved flavour not be credited, in part at least, if not altogether, to the Muscat temperature and long season's firing? I have had a limb of Gros Colman on Muscat roots, and a limb of the Muscat in bearing from the same roots. The produce of the Gros Colman in this case never coloured well, nor was the flavour better than in the same variety on its own roots in the same house, and the berries were almost jet black long before the Colmans on Muscat roots were half coloured. My own experience is that Gros Colman is good or bad in flavour in proportion as it gets a long season of high temperature.—D. THOMSON, *Drumlanrig*.

## TASTEFUL GARDENING.

WHAT is tasteful gardening? It is the touch of art applied so skilfully to Nature that a picture is evolved (often many pictures) which gives pleasure to all who see it. Even the mere superficial observer regards it with pleasurable emotions, paying involuntary homage to the impress of harmony and beauty which it bears, without any thought of how the effect is produced. It is to the higher intelligence, refined taste, and deeper culture of the more sensitive artistic temperament that it appeals with a force of meaning—a power of expression, which exalts it to a level with the highest works of art, and which it is the peculiar privilege of the true artist to appreciate fully. This latter is by far the more uncommon feeling, and that is precisely why the vulgarity of fanciful display is so common, the expression of good taste so rare. By this reasoning it is not intended to insist upon a quietness of tone at all insipid; far from it. Individuality, and the most striking contrasts, are all the more effective in combination with the repose which imparts dignity if they are not mere freaks of fancy or of fashion.

Taking some examples we may turn first to a rockery. When in harmony with its surroundings it is a feature of prime importance, always attractive, always growing in interest, whether it is on a large or small scale. When plenty of large masses of rock can be had, and the surroundings of the site are expansive, then the aim is to impart the effect of a natural outcrop of rock, very much broken it may be, yet always having the effect of regular strata, even when huge masses stand out singly. This is not at all difficult if only attention is given to stratification, however irregular in outline, and to placing every stone upon its natural bed, never allowing one of them to be set on end. The planting of such a rockery must have equally bold treatment. The tapering forms of Conifers, the pendant growth of the Silver Birch and Mountain Ash, the more compact forms of Holly, Berberis, Box, Tree Ivy, and Laurustinus are all in keeping; so, too, are Yucca, Pampas Grass, Phormium tenax, Arundo, and certain flowering shrubs. Of trailers only those of vigorous growth and striking characteristics are admissible, such as Ivy, Clematis, Cotoneaster, Escallonia, and Virginian Creeper.

On a smaller scale or in a more confined space the strata may be continuous without severe formality, avoiding the effect of or the broken joints of masonry, but having natural fissures, ledges, pockets, and nooks for alpine plants. The number and thickness of strata, form and extent of the rockery, must depend upon the available materials, the position, and its surroundings. The two most important points are natural effect and the provision of suitable places for the planting—neither of them such simple matters as they seem. It must be attractive without being obtrusive, an adjunct, a subordinate feature, of quiet tone, in perfect harmony with everything near it, really ornamental as a whole, and so rich in alpine growth as to well reward one for the close inspection which it invites.

Rock beds and borders, too, are, when well arranged and skilfully managed, very attractive, both by the exquisite beauty of form in miniature of the plants, and the novelty and change which some of them present throughout the year. Natural outcrop is the key to the successful treatment of them; portions of strata protruding out of the soil with the rock always on its natural bed. Very seldom indeed is this well done. The conception which the ordinary maker of suburban gardens has of such work is either a chaotic stone heap, or long rows of stones set on end. He altogether ignores strata or natural formation; refinement, harmonious contrast, and repose affect him not. His aim is novel, even startling effects. He is undoubtedly successful, for his mountain peaks in the guise of long pieces of stone set on end, often cocked up on a mound of earth, present themselves at every turn, and presumably gratify their proud possessor. Nor are such freaks of fancy confined to suburban gardens. They may be met with upon a much larger scale in certain public parks and gardens, where they certainly answer to the description of chaotic stone heaps. For obvious reasons one cannot point to any one of them in particular;

but to the student, or others desirous of studying really tasteful artificial rockwork, mention may be made of that in Battersea Park as one of the finest examples we have in a public garden; and in a private garden the magnificent rockery at Osmaston Manor near Derby. Both are upon a scale beyond ordinary requirements, and one regrets the rarity of really artistic rockeries and rock beds upon a small scale.

Taking next shrubby groups and belts, it is desirable to call attention to the monotonous effect of evergreens. At one time very many gardens were crowded with common Laurels. They have very generally been swept away to make room for Conifers, which have justly become so widely popular. But elegant in form, as Conifers undoubtedly are, they gain much in effect when tastefully associated with such deciduous growth as Silver Birch, Purple Plum, Mountain Ash, Purple Beech, Maples, Laburnum, and the best flowering shrubs. Under skilful arrangement all heaviness is avoided, brightness and beauty are the dominant features, the formality of a nursery show border is not present simply because of the judicious massing of colour and form which gives such scope to the artist, and enables him to impart distinct features to different parts of a garden. He especially avoids in grouping anything like a plantation, formality only being allowed in the straight lines of an avenue, yet a group of Cupressus Lawsoniana or Thuja gigantea on a steep slope may be rendered very effective, as also may other distinct groups of Birch, Holly, Larch, Mountain Ash, and many other things.

Mixed planting, too, plays an important part, and may be rendered very effective. Take, for example, a lawn group of tall columns or cones of green; the effect is stately, and it becomes decidedly pleasing by the addition of a marginal belt of flowering shrubs. There can be no objection to occasional masses consisting solely of Conifers or Holly, and single specimens may often be so placed as to impart brightness and beauty to a scene that was tame and insipid without them. For example, a group of the common Holly in the angle of a building, though healthy and flourishing, was so heavy that I was asked if anything could be done to relieve it. Certainly! Plant a Pampas Grass in front, well away from it and opposite the centre; plant in it such deep, rich, well-drained soil that fine spikes are a certainty, and every summer and autumn, while the plumes are in full beauty, the effect will be most striking, the Holly forming a foil and setting of deep green for the silvery plumes of the most beautiful of all Grasses. I know nothing among hardy ornamental plants that repays one better than it does for a carefully prepared station. Planted in ordinary soil without special care it will give spikes 4 or 5 feet high; but planted out as suggested in very deep rich soil the plant grows to an enormous size, and the spikes spring up to a height of 10 or 12 feet. Or, to take another example, a bed or group of beds was required for a turf plat visible from some of the house windows. Beds for ordinary bedding plants were suggested; but there was a flower garden near, and the advice given was to have a central specimen of Berberis Darwini with four rock beds around it, but well away from it. The rock beds had the stones arranged as has been indicated, and the planting consisted of compact growing and dwarf sorts of Heath, dwarf Kalmias, Andromedas, Gentians, Cyclamens, Primulas, Irises, Campanulas, various bulbs, and some Sedums, Sempervivums, and other alpine. The rocky masses were not obtrusive even at first, and as in due course they became partly concealed by cushions of various shades of green and grey, mingled with the bright pink masses of that most useful of hardy Heaths, Erica carnea, the effect was charming. The eye was never offended, as it is wont to be, by the bare aspect of ordinary flower beds in winter. The beds were always clothed, they became increasingly attractive year by year, and the Berberis grew into a huge, rounded mass of glossy green, enriched every spring by the deep rich yellow blossom.

I might go on to enumerate many other examples of features rich and rare in gardens, but the object of this article was to utter a protest against the growing predominance of fanciful display in gardens; of the introduction of features essentially vulgar, and of the sacrifice of good taste to a craving for startling effect.—EDWARD LUCKHURST.

### MILDEW.

AMONG the difficult and multifarious duties of a gardener's daily life is the constant warfare he has to wage in one way or another against the many garden enemies which are ever ready to attack him on all sides almost every day throughout the year, and I think of all the enemies he has to contend against perhaps mildew is the most insidious and destructive. As I am a believer in prevention rather than in cure, I will endeavour to show how through good cultivation it is possible to keep mildew at bay; but

I will first refer to the cure of mildew, and to illustrate my meaning on this point I may be allowed to relate an incident in my experience, which happened in the spring of 1870.

The previous December I had been appointed head gardener at Drayton Manor, and under my charge was a large late vinery, and a good crop of Grapes in the house was a most important consideration to meet the heavy demands for numerous shooting parties in the autumn. The Vines started and apparently went on all right until early in the month of May, immediately after which time (just as the berries had finished setting) I was horrified to find that half the Vines were badly affected with mildew, and especially the young berries, which were literally coated over with it. Being then young and new to my charge this disaster seemed to overwhelm and stagger me, and I felt within myself that my career as a head gardener had suddenly and for ever come to a close, as I expected nothing less than that my then generous and kind-hearted employer would say that this failure in the Grape crop clearly pointed out to my utter incapacity as a gardener. However, I soon overcame this feeling, and knowing from previous experience the efficacy of sulphur in the destruction of mildew, I at once decided to resort to this remedy, and being at the same time apprehensive that other parts of the Vines not then visibly mildewed might be affected I decided to apply a drastic remedy.

In the afternoon of the same day I had the Vines thoroughly saturated with rain water, and whilst they were in this condition I dredged every portion of the fruit, leaves (both under and above), and stems with flowers of sulphur, and left them in this condition until the following morning, when every particle of the sulphur was carefully washed away. I may say here that before that application of the sulphur in the afternoon until it was all washed off early the next morning the pipes were kept at a good heat, but not enough to cause fumes to emit from the sulphur.

Of course I am well aware that there is nothing new in the application of sulphur for the destruction of mildew, but many are timid in the liberal application of it in the way I have described, that I write to make it perfectly clear, to young readers more particularly, that sulphur may be liberally applied in the way I have described with perfect immunity from harm or danger; but here let me say that overheating of the pipes must be guarded against or the consequences will be fatal.

Now as to the result of the heavy sulphuring which, as you may imagine, was watched by me with much anxiety for many days. The cure as far as killing the mildew was perfect, and my feelings afterwards I remember were something akin to a boy's feelings at school when he has given another boy a good licking—a feeling which all old boys must remember—I felt that I had come off victor. I have much to thank for that experience, as mildew and I have often met since, and the old remedy remains as powerful as ever.

At the beginning of this paper I stated that I believed prevention to be better than cure, and this mildew visitation troubled me a good deal afterwards, attacking the Vines at the time it did, when they were under a great strain for a period—viz., in forming their berries, I decided there must have been something wrong at the roots, and in the following autumn I had them lifted within 2 feet of their stems and replanted in a new compost. I had the charge of these Vines for nine years afterwards, and no Vines could flourish better than they did during this time, and no trace of mildew was seen on them again.

More recently I have had Peaches to deal with badly affected in the same way, and the cure and prevention have been equally effective. The experience of many of our best practitioners may be quoted in opposition to my views on the causes and cure of mildew, and I only give you my experience for what it is worth, and I say again that a thorough application of the flowers of sulphur will destroy mildew, and I further say that a proper and generous cultivation of the roots of trees and plants will effectually protect them from its visitation.—O. THOMAS, *Royal Gardens, Windsor*.

### FERNS.

WHEN in a healthy and flourishing condition all Ferns, whether stove, greenhouse, or British, are beautiful and interesting, and well repay that attention which is necessary to obtain the best results. So varied are they in size, habit, and form that they lend themselves to be cultivated successfully under various methods, and while nearly all species and varieties succeed well under pot culture, many of them would do much better, and be more in character with the habit and general requirement of the plant, if grown in baskets or planted out. Grown thus they would, when once established, last many years, and give far less trouble.

Where proper arrangements can be made with suitable surroundings undoubtedly Ferns planted out flourish best and certainly look

more natural. For instance, one good *Dicksonia* or any other of the handsome Tree Ferns planted in the centre of a conservatory or Palm house, and encouraged to develop its huge fronds in a natural way, with a good carpet of *Selaginella* growing up to its trunk, would form a more pleasing feature than a dozen plants huddled together in pots and tubs.

Again, there are other Ferns most unsuitable for pot culture owing to their natural drooping character, but which are invaluable for baskets or overhanging rocks. Among these especially may be named the *Woodwardias* and *Goniophlebiums*, the latter requiring a higher temperature than the former to see it at its best. In the fernery here the *Woodwardias* are a grand sight; hanging over the rocks many feet, and reproducing themselves as they do from the tips of the matured fronds, is both interesting and curious. I believe it possible to have this valuable Fern in a healthy condition, reaching as much as 20 feet. To accomplish this the plants should be placed in baskets or planted near rocks overhanging water, and the foliage kept in an almost dripping state, or thrips, the great enemy of most Ferns, would soon attack the old foliage and destroy the beauty and true character of the plant. Most of the *Davallias*, too, are very suitable for rocks and baskets, their creeping rhizomes producing the most beautiful fronds, and which last a long time in a cut state. Many others could be named which are more suitable for baskets than pots. I would strongly advise those who have not succeeded as well as they would wish with that lovely Fern, *Adiantum farleyense*, to try it in baskets. I find it does much better and lasts many years without any trouble. To disturb the roots when well established is a great mistake; rather assist them during the growing season with a little artificial manure once or twice a week, and top-dress them with fibrous loam, if this can be done without injury to the young fronds. The same can be said of that most useful Fern, *A. cuneatum*. Baskets made up of this two years ago are now perfect globes of fronds 4 feet through, and which never fail to attract attention.

In selecting baskets for Ferns reject all ornamentation of wire-work. Let them be as plain as possible, but strong; the object in view should be a mass of healthy foliage, completely hiding the basket. I find the best baskets are those of a round or half globe shape. This allows the light to act on a larger surface than is the case with those with broad, flat bottoms. In making these up the best results are obtained by using one variety of Fern only in each basket. When several varieties are mixed together they soon form a mass, the stronger smothering the weaker, and resulting in an unsightly object.

At the present season, before growth is too far advanced, all Ferns should be overhauled, cutting away all old fronds which keep light and air from those that are pushing up. It may not be found necessary to disturb many of them, but it is very essential to know that the drainage is perfect, and though Ferns require a great amount of water, like other plants, they quickly resent it in a stagnant form.

Most Ferns enjoy peat, but it is a mistake to think they will not succeed without it. There are very few varieties which do not enjoy fibrous loam and leaf mould with coarse sand and charcoal added. *Adiantums* especially do better in a mixture of this kind than in peat alone. All Ferns enjoy an atmosphere charged with moisture. This being so, it is decidedly wrong to ventilate too freely, or in such a way as to cause a rush of air through the house. Where proper ventilation is provided at the top of the building this will be found sufficient, and seldom will it be necessary to add any at the bottom.

In establishments where much cut-flower work is carried on a plentiful supply of Fern fronds is indispensable. This demand should be met by growing several batches of plants in pots of the most useful kinds, chiefly *Adiantums* and *Pteris*. This can easily be done in the fruit houses, especially in vineries where they enjoy the shade from the foliage above. By this means the beauty of the fernery is not destroyed by repeated cutting.—RICHARD PARKER, *Impney*.

[No one can visit the beautiful under-glass fernery at Impney, with its bold rocks, charming vistas, pleasing water scenes, and luxurious Tree and scandent Ferns, without recognising the taste and cultural skill displayed by our correspondent.]

## PACKING GARDEN PRODUCE.

ANOTHER London season has commenced, and doubtless in more than one case the consignment of produce from the country garden to the town house will have begun. However, some time will elapse until this becomes, generally, a part of routine garden work. In the meantime, an account of my manner of packing may, I trust, be helpful. My experience is that the demand for flowers

is almost insatiable. A grower, producing largely for Covent Garden, lately told me that this market is at once the dearest and the cheapest mart of the kind in the world. Good produce, in demand and scarce, invariably sells at a high rate, while a plentiful supply makes low prices. But against this my ladies have often told me that the particular items they require, especially flowers, never fall to a price that they could with truth term inexpensive. So the old garden in the country is called upon to bear the brunt of the season.

It has been dawning on the minds of gardeners that the ways and methods of the growers for market are worth attention. For example, the market gardener does not put his merchandise in large or in heavy packages, but always in sizes that are easy to handle. Gardeners, on the other hand, are addicted to a practice of consigning in one bulky hamper, unmindful that the porters and carriers through whose hands it must pass will, naturally, exhibit less care in handling a heavy and unwieldy hamper than in those that are compact and easy to move. I believe there are to-day packers who still put together into one hamper the vegetables, fruit, and flowers of each consignment, and this, no doubt, on the double score of saving trouble and lessening expense. This, however, is a mistake. A number of light, handy parcels are in every way easier to manage than a heavy one, and the cost of transit is no more. But it must be admitted that market growers are in a position to carry out the system in a manner impossible for private gardeners to imitate. The latter are obliged to put small packages of various vegetables, or of other garden produce, into one hamper. While, however, that is so, it is nevertheless a simple matter to select and pack the heavier and coarser vegetables together, those that are light or fragile being put separately.

The hampers I use for vegetables, also for flowers, are those employed by continental firms for the transmission of Lettuces and of fruit during the winter. The hampers are of two sizes, the larger of which measures 24 by 16 by 9 inches and the smaller 18 by 12 by 6 inches. The former is the more useful, the latter being employed for carrying fruit, and only occasionally flowers. These hampers cost 1s. each, and they last three years. For the best flowers, such as Orchids, small boxes are used. These cost 1d. to 2d. each, and are bought at a store in the neighbourhood. For long-stemmed flowers boxes are specially made. These are 4 feet in length, 11 inches wide, and 4 inches deep. Square punnets, costing 6s. 6d. per gross, I fill with Mushrooms, Tomatoes, and with small fruits. They are, of course, packed for transit in one of the larger hampers. The only other material of importance is paper. This is of two qualities; a light make like tissue paper costing 3s. per ream, and in this we pack the best flowers. The other paper is of a much heavier quality, costs 5s. per ream, and is used for packing both flowers and fruit. Small string, as well as twine of moderate strength, is required for fastening both hampers and boxes. Nails are on no account used to secure the latter, but only string. Even when, as occasionally happens, two or more boxes are sent as one parcel, they are not separately fastened, but tied together. This method, which gives a security which practically is complete, is commendable on account of the saving to the boxes as well as because it facilitates packing and unpacking.

In the manner of gathering the various vegetables and out-of-door fruit there is a right and a wrong way. It is inadvisable to set several men to this work. Generally, one man is capable of overtaking it, but if more are necessary, allot to one man the task of gathering vegetables, and to the other fruit. There will thus be no overlapping, no standing in each other's way. Again, always set the same men to the same work; it is done more expeditiously, and better, and the gardener is saved much worry. I make it my special duty to gather flowers and hothouse fruits. I also superintend the packing of vegetables, and invariably pack flowers and fruit myself.

As the garden is, by road and rail, about twelve hours distant from the London house, care is required to forward at the right time and in the right way. We arrange at the beginning of each season for a low through rate, by express. The difference amounts to 1d. per pound, but as the ordinary rate is 2d., it will be seen that exactly 100 per cent. is saved. In the course of a "season" freight charges amount to several pounds. From our station many parcels can be sent as one, but from London each separate empty is charged at the same rate as a half cwt. I have also found that small parcels up to a certain weight, as a rule, are sent more cheaply and expeditiously by train than by parcel post. Flowers, vegetables, and fruit are gathered early in the morning of the day for forwarding, packed in the forenoon, and during the afternoon the hampers are sent to the station to be consigned direct to London by night express, and they are delivered early in the morning at their destination.—R. P. B.

(To be continued.)

*ODONTOGLOSSUM PULCHELLUM.*

A SPECIMEN of this pretty *Odontoglossum* has been flowering in the cool Orchid house at Kew for some time past. The spike is erect, about a foot in height, and bears ten or twelve flowers; it has a strong resemblance to Lily of the Valley. The flowers are pure white except for a yellow crest, and are very fragrant; they are smaller than the majority of *Odontoglossums*. The narrow grassy leaves are of a dark green colour, and are produced in pairs on the long thin pseudo-bulbs. This species is a native of Guatemala, from whence it was introduced about 1840. It is essentially a cool-house plant.

*ANGRÆCUM FASTUOSUM.*

This distinct little *Angræcum* has not as yet become very plentiful. It has only been in cultivation for a few years, having been introduced from Madagascar by Messrs. Sander in 1881. It is of very dwarf habit, the stems being only about a couple of inches in height. The leaves are oblong, 2 or 3 inches broad, and of a leathery texture. The flowers are very pure white and deliciously fragrant. They are about  $1\frac{1}{2}$  inch in diameter, and are borne two to four on a short raceme. A plant is now flowering at Kew.—A. B.

*CÆLOGYNE FLACCIDA.*

THE interesting note on page 153 regarding this Orchid was well timed, for although not seen so often as it deserves, there are few Orchids so easy to cultivate, or more beautiful in appearance, when a fine specimen is seen in flower. An intermediate house is the most suitable place for it, and I would strongly recommend baskets in preference to pots or pans, as then the racemes of flower can be seen to advantage. Some lumpy peat, living sphagnum moss, and plenty of water during the growing season, are all that is required to produce good pseudo-bulbs, which, with a season of rest after growth is completed, will reward the cultivator for all his trouble. We have a good plant in flower in a basket, and if wanted to last in flower over a long period, it will bear removal to cooler quarters without any apparent detriment.—R. P. R.

*CATTLEYA PERCIVALIANA.*

"H. W. W." (page 129) does well to call attention to this useful *Cattleya*, one of the most beautiful of the "labiate" section. We have several plants in flower now, some equal to *C. Trianae* in size, while far surpassing that popular species in richness of colouring. I have enclosed a flower of a pretty form, not so large as some we have, but beautifully marked. This *Cattleya*, in common with *C. Lawrenceana* and *C. superba*, will stand a greater amount of sunlight than most others, and if grown in a clear light and an average temperature it is very free flowering."—H. R. R.

*CYPRIPEDIUM JOHNSONIANUM.*

THIS hybrid *Cypripedium* is the result of a cross between *C. nitens magnificum* and *C. Lawrenceanum*, and is an exceedingly pretty variety. When exhibited by Messrs. F. Sander and Co., St. Albans, at the Drill Hall, on December 13th last year, the Orchid Committee of the Royal Horticultural Society deemed it worthy of an award of merit. The lip and petals are of a burnished purple. The lower area of the dorsal sepal is deep green, the upper portions and edges

pure white, lines of purple dots running from top to bottom. Fig. 30 represents a flower of this interesting *Cypripedium*.

## FINE CÆLOGYNES.

Two specially fine clumps of *Cælogynes* are at The Briars, Reigate. They comprise *cristata* and *cristata Lemonei*, the latter much the purest and best. These clumps are each some 4 feet over, in superb health, and covered with spikes of bloom. They are in pans 26 inches in diameter. *Cælogyne cristata Lemonei* has smoother or more perfectly formed flowers than has *cristata*, that are not only purer in colour, but have rich orange yellow throats or lips that present a most pleasing contrast to the snow whiteness of the rest of the bloom. More beautiful Orchids for the furnishing of sprays, or single blooms for buttonholes can hardly be conceived. These *Cælogynes* bloom so readily in the winter under the influence of gentle warmth, that their floral value can hardly be over-estimated.—D.

*CATTLEYA WARSCEWICZI AUTUMNALIS.*

*CATTLEYA WARSCEWICZI* (or *C. gigas*, as it was afterwards called) is well known to be a summer flowerer—that is, its blooms are produced on the young growths, without an interval of rest. A plant in the collection of Mr. F. L. Ames of North Easton, Mass., U.S.A., has for several years in succession flowered in November and December, which gives it an enhanced value for decorative purposes. After the growths are matured the plant rests for a considerable period, as in the case of *C. labiata*. This plant was introduced by Messrs. Hugh Low & Co. of Clapton, and was purchased as an imported *C. Mendeli*. Its characteristics are noted in *Garden and Forest* for 1890, p. 114.

It is interesting to record that a second plant has now appeared in the collection of W. G. Marshall, Esq., Norton Manor, Taunton, Somerset, where it flowered in December last. It is a magnificent

FIG. 30.—CYPRIPEDIUM JOHNSONIANUM.

thing, the petals 4 inches long by  $3\frac{1}{2}$  broad, and, as well as the sepals, of a light rosy mauve. The front lobe of the lip is of the richest crimson-purple, with a light rosy mauve margin. In the throat are two large straw-coloured blotches, which are yellow on the side

The copper sulphate was dissolved in a quart of water, and the calcium chloride was treated in the same way. The two solutions were then poured together and enough water added to make 5 gallons.

2.—A comparison of two fungicides containing no copper with those given under question 1. The fungicides used in this case were :

9.—POTASSIUM SULPHIDE SOLUTION.

Potassium sulphide	..	..	..	..	..	..	..	..	1 oz.
Water..	..	..	..	..	..	..	..	..	5 gallons

The potassium sulphide was added to the full quantity of water and then stirred until it was dissolved.

10.—SODIUM HYPOSULPHITE SOLUTION.

Sodium hyposulphite	..	..	..	..	..	..	..	..	1 oz.
Water..	..	..	..	..	..	..	..	..	5 gallons

This was prepared the same as No. 9.

3.—A comparison of Bordeaux mixture, full strength, with the same preparation half strength.

BORDEAUX MIXTURE, FULL STRENGTH.

Copper sulphate	..	..	..	..	..	..	..	..	6 lbs.
Lime (unslacked)	..	..	..	..	..	..	..	..	4 lbs.
Water..	..	..	..	..	..	..	..	..	22 gallons

BORDEAUX MIXTURE, HALF STRENGTH.

Copper sulphate	..	..	..	..	..	..	..	..	3 lbs.
Lime (unslacked)	..	..	..	..	..	..	..	..	2 lbs.
Water..	..	..	..	..	..	..	..	..	22 gallons

4.—A comparison of the Bordeaux mixture, full and half applied early and late. By early treatment is meant that two applications were made before the fruit set. By late, that treatment was postponed until the berries were the size of bird shot.

5.—A comparison of six treatments, using Bordeaux mixture, full and half strength, with four treatments, both beginning at the same time, *i.e.*, when the leaves were first starting."

Two vineyards were devoted to the experiments : (1) for trial of the ten fungicides, and (2) for the Bordeaux mixture at full and half strength. The treatments, six in number, in every case were made on the same day, the date for each being as follows :—

(1) April 27th (Vines just beginning to grow) ; (2) May 13th ; (3) May 25th ; (4) June 9th (foliage nearly full grown, fruit the size of bird shot) ; (5th) June 22nd (Vines growing vigorously) ; and (6) July 7th.

As regards preventives against black rot, the various preparations stand as follows :—

	Per cent.
I. Copper saccharate, glue mixture ..	100
II. Bordeaux mixture, ammoniacal solution, modified eau celeste ..	99
III. Copper acetate solution, copper chlorido mixture, potassium sulphide solution ..	96
IV. Precipitated carbonate of copper solution ..	90
V. Sodium hyposulphite solution ..	70

Nothing further was done in the vineyard until September 1st, when all the Vines were carefully examined and observations made on several points, some of which have interest for growers in this country and its colonies, especially those relating to the injury to the foliage and wood by the treatments, which are set forth in an excellent diagram herewith reproduced.

DIAGRAM 1.—Showing the average condition of the foliage and wood September 17th of the treated plats with respect to injury from the spraying. (Black indicates injury.)

FIG. 31.—DIAGRAM 1.

EXPLANATION OF DIAGRAM 1.—(1) Bordeaux mixture ; (2) Copper acetate solution ; (3) Copper chloride solution ; (4) Ammoniacal solution of copper carbonate ; (5) Precipitated carbonate of copper solution ; (6) Potassium sulphide ; (7) Sodium hyposulphite ; (8) Modified eau celeste ; (9) Glue mixture ; (10) Copper saccharate.

The above diagram illustrates better than many words the damage or otherwise of the treatments, but the benefits are given in tabular form ; therefore, to elucidate the results of the experiments, I have prepared

the following diagram, which shows at a glance the per-centage of perfect clusters of Grapes due to the several treatments, the mean per-centage of perfect bunches on the untreated, also the lowest per-centage of perfect bunches on the untreated Vines, and the maximum.

DIAGRAM 2 —Showing kind of treatment and per-centage of perfect clusters on September 17th. (White indicates perfect clusters.)

FIG. 32.—DIAGRAM 2.

EXPLANATION OF DIAGRAM 2.

	Per cent.
(1) Glue mixture..	100'00
(2) Modified eau celeste, copper saccharate, Bordeaux mixture, copper chloride mixture..	98'00
(3) Potassium sulphide solution ..	95'17
(4) Ammoniacal solution ..	91'32
(5) Copper acetate ..	90'47
(6) Precipitated carbonate of copper solution ..	86'47
(7) Sodium hyposulphite solution ..	40'78
(8) Average perfect clusters on untreated Vines ..	41'37
(9) Lowest ..	15'95
(10) Highest ..	68'00

The results of treating Vines with Bordeaux mixture at full and half strength are given below, in per-centages of efficacy :—

	Per cent.
" Bordeaux mixture, full strength, early, six sprayings ..	94'00
" " half " " four " ..	93'90
" " full " " four " ..	90'00
" " full " " late three " ..	89'00
" " half " " " " ..	23'00
" " half " " " " ..	16'00"

CONCLUSIONS.—“(1) With the exception of the Bordeaux mixture all of the fungicides used . . . more or less injured both leaves and fruit ; (2) Taking cost, ease of preparation and application, effect on foliage and fruit, and all other questions into consideration, the Bordeaux mixture, even though reduced to less than one-sixth the usual strength, proved the most effectual remedy ; (3) Vines treated with Bordeaux mixture, half strength, gave practically as good results as the same preparation full strength ; (4) In every case early treatment gave decidedly better results than late ones ; (5) Six treatments, the last two after the Grapes were practically grown, gave better results than four, the last being made when the berries were the size of bird-shot.”—G. ABBEY.

[The above record is interesting and suggestive, but in this country both Tomatoes under glass and Potatoes in fields have been injured by the “full strength” Bordeaux mixture, and a preparation of equal parts of sulphate of copper and lime have proved more satisfactory.]

GARDENERS' ASSOCIATIONS AND SITUATIONS.

I THINK “D.” in the paragraph under the above heading, page 135, touches a subject of considerable importance to gardeners, and one well worthy of discussion ; for I am of the opinion that gardeners' associations and horticultural societies do not accomplish all that they might in being of practical assistance to gardeners in time of need, nor yet in keeping up the status of the profession in these days of horticultural progress.

Why should not the Royal Horticultural Society, which is still lamenting a lack of support, and other kindred societies be of more practical benefit to gardeners, and why should not employers when wanting gardeners obtain them through these societies ?

I see the Council of the R.H.S. are fostering an idea for the making or training of gardeners. Will they also promote a scheme so as to be of assistance to gardeners when out of situations ? I take it that if the R.H.S. would undertake the recommendation of gardeners of proved abilities and character they would get a much larger share of their support than at present, and employers of gardeners might also be expected to associate themselves with the Society.—A. Yorks.

## SILVER MEDAL ESSAY.

## MANURES AND THEIR USES.

By Mr. G. A. BISHOP, *The Gardens, Wightwick Manor, Wolverhampton.*  
(Continued from page 151.)

## MANAGEMENT OF MANURE HEAPS.

THE animals should have sufficient litter to absorb the whole of the urine, which contains most of the nitrogen produced; but only this quantity of litter, any excess being objectionable. Another matter of importance is the thorough mixing of the various kinds of manure. On no account should horse manure be allowed to accumulate by itself, but it ought to be mixed with the cooler refuse of the cow and pig.

When the manure is removed from the stables, pigstyes, and cowsheds, it should be placed under cover. A good covered bin is a valuable adjunct to a farm or stable; the manure should be stored there, and frequently watered with the liquid that drains from the buildings and yards provided it is not diluted with rain or surface water.

Rain washes out much of the valuable constituents, therefore down spouts and drains should not be allowed to carry water into places where manure is stored. Where a large number of cattle are kept a good covered-in yard should be a reality, then all the litter from the stables and sheds can be placed in the yard to be well trodden down.

In order to prevent loss of ammonia by drainage and evaporation powdered gypsum may be used to fix it, sprinkling the powder on the floors of stables, over manure heaps, or in yards where manure is being trodden down. The ammonia displaces the calcium from the calcium sulphate (gypsum) and forms ammonium sulphate. Lime should on no account be employed, as it will liberate and drive off the ammonia. Kainit as containing 12 per cent. of potash is a good addition to the manure. As the manure accumulates it will probably have to be stacked out. This should be done if possible in frosty weather, when the ground is hard, a clay foundation should be chosen, and a few inches of peat, Potato haulm, or weeds and rubbish laid upon it, to absorb moisture. On this the manure is placed, forming a heap about 5 feet high, made as compact as possible, trimming it and covering with about 6 inches of soil, the top being rounded to throw off the rain.

## COMPOSITION OF FARMYARD MANURE.

	Fresh.	Partially decayed.	Much decayed.
Water ..	70.00 ..	70.00 ..	79.00 ..
Organic matter ..	24.60 ..	19.20 ..	14.50 ..
Ash ..	4.40 ..	5.80 ..	6.50 ..
Potash ..	0.52 ..	0.63 ..	0.50 ..
Soda ..	0.15 ..	0.19 ..	0.13 ..
Lime ..	0.57 ..	0.70 ..	0.88 ..
Magnesia ..	0.14 ..	0.18 ..	0.18 ..
Phosphor's pentoxid ..	0.21 ..	0.26 ..	0.36 ..
Sulphuric acid ..	0.12 ..	0.16 ..	0.13 ..
Chlorine ..	0.15 ..	0.19 ..	0.16 ..
Silica ..	1.25 ..	1.68 ..	1.70 ..
Nitrogen ..	0.45 ..	0.50 ..	0.58 ..

The above (rather a poor sample) will show the change manure undergoes during fermentation. Some of the organic matter disappears, while the water, ash, nitrogen, and phosphorus pentoxide increase.

## MANURE FOR FRUIT CROPS.

Fruit trees which have been long in bearing require more attention than they usually receive, particularly as regards their food. If they are grown in orchards the fruit is gathered and taken away, the leaves fall and are usually blown away by the wind, the grass growing beneath is often cut and made into litter or carried away green without a thought on the part of the cultivator that some provision should be made to return most or all of the elements contained in the grass, fruit, and leaves to the soil surrounding the trees. Vegetables will not succeed year after year without the ground being enriched with manure in some form. How, then, can it be expected that a fruit tree will continue satisfactorily productive in impoverished soil? A judicious use of phosphatic, nitrogenous, and potassic manures will return these elements to the soil which have been abstracted from it.

If old trees are in a bad state of health, the first thing the gardener ought to do is to learn the cause; if the roots are in the subsoil they must be pruned before feeding, because after root-pruning new fibres issue from the smoothly cut ends, and these fibres will be able to make use of the food applied to the ground. If the trees are in a bad state and the roots are not in the subsoil the cause must be looked for elsewhere. Parasites may be causing the damage, or pruning may be at fault, but more often poorness of soil will be responsible. In this case the soil must be considered, its nature and physical condition known and suitable manures applied.

Prepared farmyard manure used as a top-dressing will supply all that is necessary, particularly if it is prepared under cover and drenched with liquid manure, and also dressed with kainit or gypsum to retain the ammonia.

Liquid manure applied to orchard fruit trees in winter, and also in summer, will supply most that is required for good growth, fruiting, and a healthy condition throughout. Where the leaves do not blow away, the grass is eaten off, and mulching is done, a dressing of lime will have good results by decomposing the nitrogenous matter, so that the rain can wash this down to the roots.

If stand pipes can be placed convenient to fruit trees and connected with force pumps in cesspools, so that a hose may be attached for watering the trees, the return will be found to pay for the outlay. Liquid made from chemical manure may be used to great advantage with the force pumps and hose.

Where clay can be burnt with wood, this affords a valuable top-dressing for fruit trees.

Fruit trees that are grown by the side of the walks in the kitchen garden and against walls are not, as a rule, supplied with sufficient water to enable them to appropriate the food that is in the soil. Any of the manures mentioned for orchard trees can in this case be applied to garden trees that need support. The soil round the butt of the tree should not be dug so as to injure the fine roots which come to the surface for food. These remarks apply particularly to Strawberries, Raspberries, Gooseberries, and Currants. Good mulchings with decayed manure destroy weeds, and the residue can be raked off in the spring, when the manurial qualities will be washed out.

A few hints upon the quantities that may be safely used of the various phosphatic, nitrogenous, and potassic manures will be useful to some readers of this essay.

The sizes of the tree must be the index by which the operator must judge in manuring it. To give a pound of guano to large old or long established Apple or other trees would be like giving a fly to a lion, while to a spider it might be a good meal.

Nitrate of soda  $\frac{1}{4}$ , and superphosphate of lime  $\frac{3}{4}$ , may be applied at the rate of 2 lbs. to each tree having a root area of 8 square yards—more to an old and less to a very small tree; give three dressings each year.

Phosphoric slag or basic slag will be found to improve the colour of the leaves and increase the size of the fruit, particularly stone fruit, and can be used from 2 lbs. to each tree having a root area of 4 square yards; give three dressings each year.

Sulphate of ammonia is very active, and so soon lost that it is almost useless applying it by itself for old fruit trees.

Nitrate of potash is perhaps the best manure for supplying nitrogen and potash. The best way of supplying these to fruit trees, and to be within the reach of every gardener, is to make heaps of wood ashes, and ashes from the burning of refuse, and mix all the urine at his disposal and apply as a top-dressing; give three or four dressings each year.

Kainit will supply potash and soda, and may be used the same as nitrate of potash; give three or four dressings each year, 2 lbs. to a tree having a root area of 8 square yards.

Sulphate of iron.—This I have applied as a surface dressing upon old orchard trees which had been root-pruned in the autumn or winter at the rate of 4 lbs. to a tree with a root area of 16 square yards, and have been watered in with cesspool liquid. The fruit, which had hitherto been small and shrivelled, developed into fine specimens in succeeding crops.

The reader must not think because the quantities of manure are given above, all may be applied at the same time; they may only be applied together in right proportions.

## HOME MADE MANURE.

I have found the following very satisfactory for most plants and crops, judgment being exercised in mixing and applying, always bearing in mind the nature and disposition of the plants:—

Finely ground basic slag ..	..	..	..	..	..	20 lbs.
Sulphate of ammonia ..	..	..	..	..	..	20 "
Nitrate of soda ..	..	..	..	..	..	40 "
Bone ash (powdered) ..	..	..	..	..	..	40 "
Kainit ..	..	..	..	..	..	40 "
Nitrate of potash ..	..	..	..	..	..	80 "

These ingredients should be finely powdered and thoroughly mixed immediately before use. The mixture will be found to contain about 7 per cent. of phosphorus pentoxide, 6.5 per cent. of nitrogen,

14 per cent. of potassium, and 10 per cent. of lime. The phosphorus pentoxide, potassium and calcium will be in a form readily available by plants. If it is supposed phosphates of the soil are deficient, a dressing of superphosphate of  $1\frac{1}{2}$  lb. to 8 square yards will be found to supply the deficiency.

#### NEW ORCHARDS.

Where fruit orchards are about to be made, and there is time to wait, the ground ought to be prepared twelve months prior to planting. If the soil is poor trench the ground 2 feet deep. Remove the first spit of the trench, which should be 2 feet wide; also remove the bottom spit. Remove the second top spit, and carry all three spits to where the trenching will be finished. A good dressing of manure should be placed in the trench, and the second bottom spit thrown upon it. Another good dressing ought to be placed upon that, when the third top spit should be thrown upon the second layer of manure, or in the position whence the first spit was removed. There will always be two trenches open. An ordinary garden crop should be grown upon the ground the first year, and in the autumn the soil should be again trenched. Any addition of manure must be left to the discretion of operator. When the ground is trenched the second time the manure will be so incorporated with the soil that in whatever direction the roots may go food will be found, and not in quantities large enough to cause gross growth.

If the soil is in cultivation, and there is a large quantity of humus present, some superphosphate, half-inch bones, and old mortar rubble should be incorporated with it, and dressings of new lime spread upon the surface after planting. Farmyard manure should not be used, as it will cause too gross growth. Phosphatic, nitrogenous, and potassic manures, applied as directed will give stimulus to the tree and also act upon the constituents of the soil without injurious effects.

#### WALL FRUIT.

The borders for Peaches, Nectarines, Plums, Cherries, and other wall fruit should be prepared with as much care as the Vine border if first-class fruit is required. The soil should consist of the best retentive fibrous loam, and the proportion of other ingredients added as given below. To each ton of loam add

- 1 cwt. of burnt soil and wood,
- 14 lbs. animal charcoal,
- $\frac{1}{2}$  cwt. cow and sheep manure,
- $\frac{1}{2}$  cwt. mortar rubble,
- $\frac{1}{4}$  cwt.  $\frac{1}{2}$ -inch bones.

The whole should be well mixed, but before the border is formed the drainage should be seen to. If the soil is sandy on gravel no drainage material need be put in; but if the subsoil is clayey and impervious to moisture the drainage must be effective. Place old bricks and large stones or cinders in the bottom with mortar rubbish or cinders upon them; next a layer of turf, grass downwards, after which fill in the compost, and plant the trees with great care. After they are fairly started weak solutions of cesspool liquid, 1 gallon to 6 gallons of clear water, may be given at intervals till the fruiting period, when a dressing of nitrate of potash with equal parts of bone ash or superphosphate can be given and watered in if needed. The quantity to apply must be judged by the condition of the tree. Phosphoric slag may be given as a substitute for superphosphate, particularly if the leaves are inclined to be of a yellowish green colour. The advantage of phosphatic manure is that it assists in the formation of the stones in fruit. When the trees show signs of being exhausted cesspool liquid diluted with its own volume of water, and also guano at the rate of 2 lbs. to 30 gallons of water, may be given to each tree in hot weather.

#### VINES.

The compost for making Vine borders should be constituted in the following manner:—To each ton of good loam add

- 1 cwt. of burnt soil and wood,
- $\frac{1}{2}$  cwt. of animal and wood charcoal,
- 14 lbs. of half-inch bones,
- $\frac{1}{2}$  cwt. decayed cow manure,
- $\frac{1}{2}$  cwt. old mortar.

After the drainage is perfected the border should be formed of the well mixed compost. The quality of the border near the surface would be improved by adding a little nitrogenous manure and readily soluble phosphate.

When the Vines are started weak solutions of cesspool liquid may be given, the strength to be one to two buckets to 20 gallons of water,

according to the quality of the liquid. About four applications with this solution will suffice for the first year, and any other waterings must be with clear water.

In the second year apply one dressing in the early spring, and one in the late summer, with basic slag and bone ash at the rate of 20 to 25 lbs. per Vine border 25 feet by 15 feet. A watering may be given with a solution made from the "home-made manure," at the rate of 1 to 2 lbs. per 30 gallons of water, any residue left in the tank to be thrown upon the border.

For the third year two waterings in early summer, and one at the colouring period of the Grapes, of the solution of the home-made manure, should be given. Water also when required with a solution

FIG. 33.—MR. G. A. BISHOP.

of 1 lb. of guano to 20 gallons of water. The undissolved parts from the guano and the home-made manure ought to be spread upon the border.

#### FRUIT BUSHES AND RASPBERRY CANES.

The bushes should be planted in well-prepared soil, and be watered carefully with weak solutions of liquid manure till they are well established, when good drenchings of liquid manure from the cesspool stand pipes should be given. In the spring give a dressing of the "home-made manure" at the rate of half a pound to the square yard.

#### STRAWBERRY PLANTS.

For new beds of the Strawberry plants the soil should be well trenched and manured, as recommended for the preparation of the ground for fruit trees, and its physical condition must be considered. Heavy land needs materials for improving its texture by adding sand, burnt soil, leaf mould, or road scrapings; and by increasing the retentiveness of light soils we increase their value.

The Strawberry plantation here, which is a very large one, is formed upon a sloping piece of ground which falls 12 inches in the yard. The soil itself is only 4 inches deep, resting on sand, and the red sandstone rock is in some cases only a foot or two from the surface. Nothing is done to the plantation only to mulch with good manure in the autumn. Three successive crops have been gathered, and fine fruit is produced; the weight per root has been as high as 2 lbs. Where old beds are in a bad state it would be waste of money and time to try and improve them; have plenty of runners layered, and make new plantations in September. Prepare the soil as I have suggested, and good results will reward your efforts.

(To be continued.)

[We have pleasure in publishing a portrait of Mr. G. A. Bishop in connection with this admirable essay, which doubtless many of our readers will peruse with interest.]

**THE WEATHER IN LONDON.**—The weather during the past week has been of a changeable character. Sunday opened wet, rain falling heavily during the morning. Monday morning was fine; but before noon it rained, and continued so all the day. Tuesday was bright and fine, but at the time of going to press it is raining. Much rain has fallen, and floods are prevalent in the south.

— **SEVERE WEATHER IN YORKSHIRE.**—Writing under date February 28th Mr. A. J. Temple, of Eshton Hall Gardens, Gargrave, Leeds, says, "We had nearly 18 inches of snow on Sunday last, and 18° of frost this morning, with every appearance of it lasting."

— **WEATHER IN THE NORTH.**—February leaves us in wintry garb. There has been more or less frost on every morning during the past week, 13° on the morning of the 25th and 9° on that of the 26th. That day was one of the worst we have had all the winter. From early forenoon for about eight hours a fierce snowstorm raged from the N.E., which appears to have prevailed over the whole country. The ground is under snow, and last night we had 16° frost.—B. D., *S. Perthshire*.

— **HORTICULTURE IN SCHOOLS.**—In giving a lecture on "Hardy Fruits" before the members of the Scottish Horticultural Association recently, Mr. A. F. Barron of Chiswick remarked that he was in favour of horticulture being taught in schools. "It would," said the lecturer, "be of far more use to many in their later years than the Greek and Latin that they were at present being taught."

— **THE NATIONAL CARNATION AND PICOTEE SOCIETY.**—According to the sixteenth annual report the Southern Section of this Society continue to make progress. There has been a large accession of new members during the past year, and the financial statement shows a substantial balance. The annual Exhibition of Carnations and Picotees, held under the auspices of the Society, will take place on Tuesday, July 25th, at the Drill Hall, Westminster, in connection with the meeting of the Royal Horticultural Society.

— **TECHNICAL EDUCATION IN HORTICULTURE.**—For some weeks past Mr. R. G. Waterman has been delivering a course of lectures in Christ Church Schools, Ecclestone, a portion of the County Palatine of Lancaster. The subjects treated have embraced the cultivation of Tomatoes, Apples, Cucumbers, small fruits, vegetables, and market flowers. G. Gamble, Esq., Ecclestone Park, presided at the meetings, which were very good, and the lectures have been highly appreciated.—R. P. R.

— **THE NATIONAL AURICULA AND PRIMULA SOCIETY.**—The seventeenth annual Exhibition of the Southern Section of the above Society will be held in the Drill Hall, James Street, Westminster, under the auspices of the Royal Horticultural Society, on April 25th. In issuing the report for 1892 the Committee testify to a still increasing interest in the cultivation of Auriculas and Primulas. Mr. James Douglas, Barking Side, Ilford, is the Honorary Secretary.

— **PEACH BUDS DROPPING.**—For many years I was troubled with Peach buds dropping, although the trees received a good watering after the fruit was gathered. But since I have given them another good watering, and sometimes two during winter, I have not been troubled with the buds dropping. I think this is why the buds do not drop off from trees outside, as these get a plentiful supply of water during winter, although they are sometimes very dry in the autumn after the fruit is gathered.—ALPHA.

— **PRIMULA OBCONICA.**—This free flowering Primula is very easily raised from seed sown in March and put in pots when ready, the largest plants ultimately filling 7-inch pots, the smaller being very useful in those 4 inches in diameter. Placed in a temperature of 50° flower spikes are freely produced all the winter, and continue to do so until April. For cutting the blooms are prized, lasting quite fresh in water ten days or more. Those who have not tried this plan of raising a stock of plants would do well to invest in a packet of seed forthwith.—E. M.

— **DEATH OF MR. GEORGE PHIPPEN.**—We regret to record the death of Mr. G. W. Phippen of Reading, which took place on the 23rd ult. Mr. Phippen was quite a young man, being in his twenty-ninth year.

— **THE GENUS DIANTHUS.**—Mr. F. N. Williams, F.L.S., has prepared a monograph of the genus *Dianthus*, which has been published in the journal of the Linnean Society. Mr. Williams describes 238 species and a number of hybrids.

— **WAKEFIELD PAXTON SOCIETY.**—At the recent meeting of the members of the above Society Mr. W. Daniels of Dewsbury read a useful and practical paper on "The Azalea." Mr. Brown presided, and the vice-chair was filled by Mr. George Gill. Mr. Daniels was heartily thanked for his paper.

— **EUONYMUS LATIFOLIA VARIEGATA.**—For conservatory decoration this is a most useful plant. It is, moreover, tolerably quick in growth for a plant of its kind, for in three years from inserting the cuttings it is possible to obtain excellent bushy plants in 5-inch pots. Low standards of this plant are also very effective. They soon form stems, but for this purpose are better worked on a strong-growing green variety.—W. B.

— **VINES AND CLOSE PINCHING.**—I quite agree with Mr. Stephen Castle's opinion (page 155) on the above subject. Last season two vineries, side by side, consisting chiefly of Black Hamburgs, were started about the same date. One was pushed more than the other, and being earlier it received more attention, and the Vine laterals were kept closely pinched. The other being later came in at the busy season, and the Vines were allowed to grow some length after the first stopping. The result was the Vines in the earliest house produced larger bunches with finer berries, and of a better colour. The Grapes in both houses had finished ripening by the beginning of September.—G. F., *Trafalgar*.

— **LEE, BLACKHEATH, AND LEWISHAM HORTICULTURAL SOCIETY.**—The usual monthly meeting was held on Friday evening last, at the Institute, Old Road, Lee, when Mr. H. J. Jones, F.N.C.S., F.R.H.S., the well-known Chrysanthemum grower of Ryecroft Nurseries, Lewisham, gave a paper on "Chrysanthemums and Their Culture." The room was crowded to excess by an enthusiastic audience, and the lecturer was listened to with the most marked attention, but owing to the very able and practical way with which he treated his subject very little room was left for discussion. It is to be hoped that Mr. Laing of Forest Hill will have an equally successful audience on March 24th, when he intends reading a paper on "Tuberous Begonias."

— **ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER.**—Arrangements have been made to hold a grand Exhibition of Orchids and other plants in the gardens, Old Trafford, under the auspices of the Royal Botanical and Horticultural Society of Manchester. The Show will open on Friday, May 19th, and close the following Thursday, May 25th. A liberal schedule has been prepared, and for the best miscellaneous collection of Orchids in bloom open to amateurs, the sum of £30 is offered as a first, and £20 as a second prize. Similar prizes will be given for Orchids staged by nurserymen, besides many of a smaller amount. Liberal prizes are likewise offered for groups of greenhouse and stove plants, and collections of hardy flowers.

— **SOME FINE FREESIAS.**—The finest *Freesia refracta alba* and *F. Leitchlini* that I have ever seen flowering at one time is in the garden at Corhampton House, near Bishop's Waltham, the residence of Colonel Campbell Wyndham. The plants are in five dozen 48-sized pots, averaging five bulbs in each pot. The growths, including the pots, range from 18 inches to 2 feet high, and there are fully 600 spikes of bloom expanded at one time, each spike averaging eight flowers. The bulbs, Mr. Cawte informed me, are potted in August in a compost consisting of three parts fibry loam, two parts peat, one part dried cow manure, and a free admixture of sharp silver sand. The pots are at once plunged to their rim in coal ashes in a temporary frame out of doors. The frame is covered with wooden shutters until the new growth is an inch high, when light and air is admitted freely, excluding frost of course. When the shoots are 4 inches in length the plants are carefully staked and removed to a shelf close to the glass in the greenhouse, where the night temperature does not exceed 50°. Water is freely yet carefully supplied to the roots, the house being well ventilated. Here they remain until the flower buds show, when they are removed to the front stage.—E. MOLYNEUX.

— EXPORTATION OF RHUBARB AND CELERY.—The exportation of foodstuffs from England to the United States would be a strange reversal of the order of things now prevalent. But, according to Dr. Fream, it has been attempted by a Yorkshire farmer, and the experiment is such as to deserve success and to attract imitation. From a farm less than six miles from Leeds he has exported 10 tons of young Rhubarb, which reached New York in time for the Christmas markets. The Rhubarb was forced in sheds, and was packed with straw in hampers for exportation. Besides Rhubarb, other succulent products, such as Celery, afford sources of profit to farmers near the large towns of Lancashire and the West Riding. Much cultivation of this character is carried on in the neighbourhood of Selby.

— GOOSEBERRY TREES AND SOOT.—Not far from where I live there is a field of 100 acres, let out in allotments of from one to several acres, all being under cultivation as a market garden. While one person devotes his whole piece to vegetable culture, others will grow nothing but fruit. Gooseberries are perhaps the most important crop, the fruit being gathered green for supplying early markets. The situation is well sheltered from the north-east by a wood of Scotch Fir. In some instances no other stimulant is given to the trees but soot, and so well do they look that it is no wonder the owners adhere to the following practice. In February the soil between the trees is forked over and a heavy dressing of soot given, in some cases it is spread an inch thick. It is allowed to lie for a week or two, when it is lightly forked in. If placed in contact with the roots in such quantities when fresh it might injure them. I have never seen trees looking so well. In nine cases out of ten they are never pruned.—E. M.

— PANSIES IN WINTER.—I am unable to write so strongly on the keeping properties of Pansies throughout the winter as I can of Violas, but I imagine that what suits the one would apply precisely to the other. We grow several thousands of blue, white, yellow, and others, such as Countess of Kintore, and find no difficulty in maintaining a good stock by striking cuttings every year. About the end of September we take off as many young shoots as possible, cut each to a joint, and dibble them in boxes or in some slight boundary made bed. The only protection they receive are the plank sides made in the shape of a frame and some light coverings made of Willesden prepared paper which has been tarred. These coverings are removed daily unless frost or exceptionally wet and stormy weather prevails. By the spring we have a large stock of well-rooted plants, which are removed to their summer positions as early as possible; they then get established and bloom all through the season. Many are left for the second summer, when they bloom early and profusely, and very rarely do we lose any. After that they are destroyed and younger plants take their place. Hitherto I have not had the least difficulty in keeping Violas, and I would recommend "D., Deal," (page 130), if he is not in the habit of doing so, to try and root cuttings yearly about the time he would Calceolarias.—J. W. MOORMAN.

— CYCLAMENS AT HAM COMMON.—It is almost only at the market growers of the Cyclamen that a really fine show of these beautiful winter flowers can be seen. I saw such a display the other day at Mr. J. Walker's market garden. One long house of 150 feet, a low span with 4-feet stage on either side, full from end to end, with myriads of plants in beautiful bloom. Whites largely predominated, although there were many lovely rose, cerise, and deep red flowers. The plants were all in the regulation 48-sized pots and in excellent health. Seed is usually sown in September rather early, though some growers prefer the month of August. However, it is of not much use to have Cyclamen largely in bloom until Chrysanthemums are past their best. There was in another house a number of seedlings, each having now about two leaves. These are from an early autumn sowing and are still in the seed pans, pots, and boxes, for these receptacles vary. Mr. Walker prefers sowing thinly, picking first all the finest seeds. In small 32's about twelve seeds are sown thinly, and in 6-inch pans about twenty seeds. Thus carefully sown the seedlings come evenly and do not need transplanting until the spring, when they go direct into 60-sized pots. Later they are potted into 48's and then that labour is over. The base of the soil in the seed pans is rather turfy loam, and on that is laid half an inch of finer and slightly peaty soil, as this, though long in the pans, does not become hard set. The smaller or more imperfect seeds are sown separately, and on the whole these show weaker leafage. Many of them later are rejected. Mr. Walker rarely takes more than two seed pods from a plant, as he believes firmly in securing fine seeds rather than having double the number of weak ones.—A. D.

— BEGONIA SEMPERFLORENS ATROPURPUREA.—Attracted by the descriptive remarks of this variety I was tempted to purchase a packet of seed on trial last year, and have been more than pleased with the results. The seed was sown at the end of February, and in due course the young plants were potted. The seedlings grew quickly, and by the end of June or early in July I had them planted on a warm border, where they attracted great admiration from their glossy metallic brownish red foliage and orange carmine flowers, the mixture and variation of the combined colours being something new and novel. After the first frost the plants were lifted, placed in 48-sized pots, and allotted the cool end of a warm greenhouse, where they have remained in good health all the winter, making short stubby growths. These, when taken off with a heel or at a low joint, root readily. I have now a fairly large stock, and intend bedding them out during the forthcoming season. As a packet of seed can be procured for 1s. 6d. I strongly advise your readers who have the convenience of a warm greenhouse to give it a trial.—J. W. MOORMAN, *Dulwich Park*.

— LECTURES ON "PLANT LIFE."—Professor Denny of Firth College recently gave the first of a course of six lectures on this subject in the boys' schoolroom, Lord Street, Park, Sheffield. There was a large attendance, many of the audience having to stand throughout the proceedings. The chair was taken by the Hon. Secretary, Dr. Manton, who, in welcoming the lecturer, pointed out that the course of lectures ought to be exceedingly interesting to local florists and gardeners, who were daily watching the phenomena of germination, growth, development, reproduction, and death. In an interesting address Professor Denny pointed out that no scientist, no matter how great, had been able to solve that mystery of mysteries—life. Interesting details were given with regard to the power plants have of accommodating themselves to circumstances, and how they are influenced by their environments. Illustrations of the phenomena of development and degeneration were exhibited and explained, and many interesting deductions drawn from parallel examples in the animal kingdom of to-day and by-gone ages.

— TRANSGRESSING FIG TREES.—Fig trees are not altogether uncommon in Devon, but a couple at Croyde, near Barnstaple, have says the "Western Morning News," made themselves famous by disobeying the law. They have been reported for obstructing the thoroughfare, and are in some danger of suffering for their transgressions, but even the iron hearts of the Highway Board were touched with pity and admiration for the two dumb trespassers. Splendid specimens they evidently are of their species, and their charms have given the farm its name. "We ought to be lenient with them," urged a member, "they are really natural curiosities." Another remarked that they were "splendid trees," so that they must be princes amongst the Fig family of Devon. "But they'd pull a man off the box," urged a Philistine. But the Board were too much impressed with the beauties of the trees, and so the owner will be asked to prune them "a little," just as little, it is to be hoped, as he can. Perhaps a little tying back of the obtruding branches would also be useful. There will now be some pilgrimages to the giant Fig trees, and the owner might be able to "improve the shining hour."

— BOTANICAL LECTURES.—Mr. F. E. Weiss, Professor of Botany at Owens College, recently began a series of twenty lectures on botany at the Botanical Gardens, Old Trafford, Manchester. The lectures are under the auspices of the Lancashire County Council, and are intended mainly for gardeners. Professor Weiss pointed out how important it is that horticulturists should know something about the life of the organisms with which they have to deal. A knowledge of vegetable physiology was perhaps more important to them than the ability to classify plants in their different natural orders. After dealing with the general distinction between green plants which obtain their food from inorganic sources and colourless plants which can only live parasitically on organic substances, he proceeded to speak of the structure of the seed of flowering plants, calling attention to the seed-coat, to the stored up food material, and to the embryo. Some seeds, he said, were extremely tenacious of life. It was perhaps a moot point whether grain found in old Egyptian tombs retained the principle of life, but it was a fact that Strawberry seeds taken out of a pot of jam had afterwards germinated. He explained in detail the process of germination and the conditions favourable to it.

— FROZEN NEW ZEALAND FLOWERS AT IPSWICH.—On Friday last an interesting exhibition of frozen flowers from New Zealand was made by Mr. E. H. Fison at the Art Gallery, High Street

Ipswich. The flowers were arranged on a table in the centre of the gallery. There were in all thirteen specimens, embedded in blocks of ice on basins. The flowers, though slightly damaged, owing to the Customs House officials in London having opened the cases, were in good preservation, but in the brighter varieties the colour was fading. Perhaps the best specimen was a Marquise de Castellane Rose, the petals of which looked in as good order as if just cut. Another favourable specimen was an Erica. An Andromeda was also noticeable. The flowers were white, and in form not unlike the Lily of the Valley. Some Carnations, with the exception of their losing colour, seemed not to have suffered much from their long voyage. Amongst other specimens were an evergreen shrub, some Gladioli, a Milla, Rhododendrons, Boronias, seedling Roses, and Lilies. All the specimens exhibited were grown in November within twelve miles of Wellington, New Zealand. On the table were some fine home-grown Hyacinths, Tulips, and Ferns, which gave the gallery a pleasing appearance.

— WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—  
A meeting of the above Society was held in the Mechanics' Institute on Thursday last, when the Rev. G. H. Spooner, Rector of Woolton, presided. There were two questions placed in the box for answers to

FIG. 34.—MR. A. MACKELLAR.

be given:—First, Which is the best way to fertilise Peach blossoms to insure a good set; second, Whether cuttings or old plants of *Chrysanthemums* are best to grow as trained plants. To the first question, Mr. J. Stoney, Allerton Tower, an excellent cultivator of the Peach, advocated the use of the syringe; and in the second case, Mr. W. Wilson, as an exhibitor of trained plants, advised the use of cuttings struck annually and early. Mr. R. G. Waterman then read a practical paper on "Soils, and How to Treat Them." Mr. A. Rowlands next read his prize essay on "Hardy Plants Suitable for a Cottage Flower Garden." The Chairman, in handing the prize to the essayist, said it gave him great pleasure to preside at the meeting, and heartily congratulated the winner. He also referred to the success of the Secretary, Mr. W. Disley, who was absent that evening owing to his reading a paper on "Useful Border Flowers for Cutting" before the members of the Manchester Horticultural Improvement Society, and for which he had been awarded the second prize, the competition being open to Lancashire and Cheshire. The Chairman offered a prize of 1½ guinea for an essay, the subject to be chosen by the Committee, for competition amongst the members. A hearty vote of thanks to the Chairman concluded the meeting.—R. P. R.

#### SUNNY SANDRINGHAM.

A PRETTY little wayside station, with promise of ample leafage around it in the summer time and within a few hundred yards of the coast line moistened by the waters of the Wash, such is Wolferton. One would be tempted to regard it only with the idle and motiveless

admiration awakened by many a similar station in other parts of England if it had no special associations to quicken dormant interest into active life, but it is the stopping place for Sandringham, the Norfolk seat of H.R.H. the Prince of Wales; consequently, even those who are passing through, on their way, possibly, to the pleasant seaside town of Hunstanton, arouse themselves and survey it with a certain curiosity. Stations are by no means all alike. They have characters of their own, some bustling, others sleepy, some dignified, others dilapidated, and to go a step further, despite an ardent admiration for, and sympathy with, Mr. Ruskin, to whom railways are as pernicious as manufactories, some are ugly, others are beautiful. Wolferton in the concrete has nothing special about it, but in the abstract it enjoys a vague dignity almost more noteworthy than its charming surroundings.

From the sea level on which the station stands the ground rises unmistakably landwards. A stiff hill marks the first decided stage in the upward tendency, and it is supplemented by more gentle ascents which are skirted by broad slopes of wood and Heather. Eight miles away through the Brake, green in the summer time, but now browned by the autumnal sun, lies King's Lynn; across the Wash, its waters flashing in the sun as they spread away from the coast line below, is Boston. A visitor winding his way along the delightful country road on a sunny February morning, when the Fern is bending beneath the first mellow breezes of spring, and the air is spiced with Fir-fragrance, will find beside and behind him pictures that may prove potent enough to lengthen the duration of his journey, even if he be anxious to complete it. It will be strange, too, if visions of the spring and summer beauty, which it must certainly possess, do not suggest themselves to him, transforming the Bracken from brown to green, and clothing the trees with foliage that will shimmer cool in the hot sun haze. If the way be full of attractiveness while yet the fronds remain uncoiled and the buds unbroken, it must have charms of no common kind when Nature is full of pulsing life.

To paint a word picture of Sandringham at once artistic and complete would need a broad canvas and a subtle hand. The task is embarrassing because of its many-sidedness. The great estate is equally remarkable from the point of view of the forester, the sportsman, the farmer, and the gardener. For the one there is the woodland, for the other the cover, for the third the fields, and for the fourth the fruit, vegetables, lawns, and flowers. To most readers of these columns the latter would be the most interesting feature. Their thoughts would turn from the furrow to the flower garden, from the kennels to the vineries, Peach houses, and stoves. Sandringham from the gardenesque standpoint—that is how they would regard it, and it is from this position that I venture on a few reflections suggested by a chance visit and an hour or two under the guidance of Mr. A. MacKellar, who, qualified by experience gained at Hopetoun, Tynningham, Chatsworth, Penrhyn, and ten years as head gardener at Floors Castle, the Duke of Roxburghe's beautiful seat near Kelso, has proved himself in every way worthy of the post to which he had the honour of being called two years ago. Gardeners in general will not examine without interest the portrait (fig. 34) of one of their craft, who, while still comparatively young, has risen to one of the most distinguished posts in the profession. Moreover, those who have their spurs yet to win might do worse than imitate the energy and the unwearying devotion to duty, which, combined with cultural skill and a modest unassuming disposition, have secured Mr. MacKellar what he most prizes, the confidence of those whom he serves. Complete subordination of self to work and concentration of thought upon the fullest development of beauty and utility in his sphere of labour are characters which impress themselves as dominant in the present head of the gardens at Sandringham.

Leaving for the time being the fruit and vegetable gardens, also the plant and fruit houses, a few words shall be devoted to the pleasure grounds and flower gardens around the mansion. February is not, it will be agreed, the month to see them at anything approaching their best, but they are by no means devoid of attractiveness even at this unfavourable season. The mansion, to which an extensive wing has been added since the fire some time ago, is a long and not very lofty building with a considerable frontage, and stretching away in front of the windows is an extensive series of beds which in the summer are gay with flowers. Though necessarily less brilliant now they are little less beautiful, for they are planted with a great variety of small shrubs, the green, golden, and silvery tints of which make them cheerful in the dull season. Golden Yews, Berberises, Golden Hollies, Portugal Laurels, Golden Box, Aucubas, Euonymuses, Retinosporas, and many others are blended in a tasteful and effective manner. No more striking example of the possibilities in winter bedding could be afforded than is here provided, and the contrast between the system and an imaginary array of empty beds and bare soil is vividly presented. Thousands of bulbs also occupy the beds, and throughout the spring they will lend the brightness of their rich and diversified colours to the scene. Rhododendrons, too, will contribute, large quantities of choice named varieties being planted and retained until their flowering period is over, then lifted to make way for summer plants.

Through banks of these beautiful plants, amongst numbers of shapely Conifers, and by groups of shrubs, the visitor finds his way to the "Church Walk," a delightful avenue lined with lofty Scotch Firs their trunks hidden in clustering masses of Ivy. At the end is the beautiful little church, it and its approach constituting one of the most charming pictures which could be found, not only at Sandringham but in the whole country. Then there is the lake, widening and narrowing, advancing and receding, with quiet pools at the foot of shelving boulders

of rock. Water looks at its best, of course, when it is lying placid beneath a fierce summer sun, and it is easy to conceive how delightful the lake must be in the hot weather. Almost at right angles is another sheet of water, immediately under the windows of the residence now being prepared for the Duke of York. This encircles an island which is being laid out and planted. Through the noble old Oaks on the left of the dwelling stretches the extensive park with its thousands of deer, presenting a splendid view from the banks of the stream. A ramble through the grounds from this point to the kennels and the keeper's house at the top, and thence back towards the mansion, is full of pleasure, new beauties unfolding at every step. No tree-lover could fail to observe with pleasure the thousands of graceful Conifers, with which the grounds are full. Amongst them are some magnificent Wellingtonias, fine *Picea nobilis* and stately Cedars. They are much too numerous for individual notice, and form, without doubt, one of the finest features of the place. It is not a question of a few isolated giants, for the soil

said in reference to the grounds at Sandringham, but considerations of space demand that attention should be given to other features of the estate. I should like to pause for a few moments, however, to express a more than superficial admiration for the houses in the occupation of the head officials with which the grounds are dotted. On few of the great estates in the United Kingdom is such provision made for the workers on them as exists at Sandringham. The residence of the head-keeper is a most beautiful one, and equally so is that of Mr. MacKellar. It will not be without interest to reproduce a photograph of the latter dwelling in order to show, so far as is possible with an engraving (fig. 35) the consideration in one important respect which is shown to those who are fortunate enough to be chosen for filling responsible posts by the Heir to the Throne of Great Britain. With its projecting eaves and covering of Wistaria and Roses the house presents an aspect which can hardly fail to charm, while within it is roomy, cheerful, and comfortable, new wings having been added to increase the convenience of its occupants. Within

FIG. 35.—THE GARDENER'S COTTAGE AT SANDRINGHAM.

hardly has substance enough to produce many specimens of the largest size, but of a vast and varied collection of medium-sized handsome trees. Nothing adds more distinction to a garden than well-managed Conifers, and at Sandringham they play a most important part.

Not far from York Cottage is the beautiful wild garden, full of Rhododendrons and other shrubs now fast swelling their buds. The slopes and recesses suggest delightful pictures in the springtime, when the larger plants are in full but tender leaf and the thousands of Primroses and other flowers are at their best. Already patches of Snowdrops are whitening the grass, and later on Daffodils will lend the help of their graceful flowers and quiet harmonies of colour. Much has been done and much more is being accomplished to add beauty and interest to this and other parts of the grounds. Even now they are far from being unworthy of the place, and there can be no doubt that the steps which are being taken in the development of many special features and in the planting of shrubs and flowers will greatly enhance their attractiveness. A winter tennis court with rustic houses connected is discovered hidden away among the trees, and must form a most pleasant resort when the turf is rendered unsuitable for play by the weather.

Much could be written in addition to the few words which have been

and without there is that air of beauty, comfort, and happiness which tends to sweeten life so greatly. A few hours within its walls convince the visitor that Mr. and Mrs. MacKellar are as anxious to prove themselves worthy of the many kindnesses bestowed upon them as they are deeply sensible of the good fortune which has befallen them in having the privilege of serving where service is at once a pride and a distinction.

In speaking, as I hope to do in a future issue, of other features of the gardens at Sandringham, I shall refer to the splendid provision that is made for the under gardeners, but I should like, while referring to the dwellings on the estate, to say a word about those provided for the labourers. At one end of the grounds is what might be termed the model village of West Newton, a cluster of sound, well-built, comfortable cottages, with large gardens attached, which the occupants are encouraged to keep cheerful and productive. There is, too, a club and library, where the men can assemble after their work is over, and, without payment, read the newspapers and books provided for them. In another part a school is maintained by the Princess of Wales. Full employment is always found for the men at a higher rate of pay than is given elsewhere. Moreover, the utmost consideration is extended in respect to the hours of labour. From the 1st of November to the 1st of

March the workmen leave at 3 P.M. every day, and although the hours are of course longer in the summer, the average working day throughout the year is less than eight hours. It is pleasant to record such facts as these, proving as they do beyond all dispute by the bitterest critics of royalty that a blind selfishness is not the invariable ruling passion in those whose path in life is exalted. Those in closest association with the Prince and Princess of Wales speak of never-failing courtesy and kindness, and the conditions of life which prevail amongst the workers at Sandringham have only to be imitated elsewhere to bring happiness, contentment, and prosperity to rural England.—W. P. W.

(To be continued.)

#### THE NATIONAL CHRYSANTHEMUM SOCIETY.

HAVING nothing at stake I did not avail myself of the first invitation to attend the annual meeting of the National Chrysanthemum Society; but in order to test the clique question I embraced the first offered privilege to nominate a few well known country growers. Knowing the certainty that no outsider stands the least chance of being elected on the Committee I did not take the trouble to ascertain whether my nominees would accept office, and I here tender them my humble apology for using their names entirely without their permission.

However, the results of the recent election proceedings is a very faithful illustration of the late controversy published in the *Journal of Horticulture*; and as it is reported the Society has benefited by this said correspondence, it may be hoped the Editor will extend the privilege, as it appears the Society still needs all the assistance it can obtain.

I am glad to see that a more modern system of electing members of the Committee is likely to be introduced, for surely the primitive method of merely showing hands can hardly be accepted as satisfactory, especially where it has to be repeated several times over, according to the number of nominations, and this in a crowded room. In these days of enlightenment, easy communication, and cheap postage, the elections ought to be made by ballot. This could easily be managed by the use of postcards. Then every member, however remote, could record his vote cheaply and efficiently, and thus make the Society in reality "national" instead of what it is at present.—J. H. GOODACRE.

#### ELECTING OFFICERS.

I HAVE so much sympathy with your remarks with respect to the way in which the election of the N.C.S. Committee members were recently elected by show of hands, that in submitting the code of rules adopted from Gardeners' Association here, I got a clause inserted that all contested elections should be by ballot. That was done to prevent any jerrymandering of the election by show of hands, as in our case the attempt to elect twelve members out of seventeen nominated on to the Committee would have led to endless trouble and misapprehension. All the names were written in chalk on a board, then each member was supplied with a piece of paper on which to write down his favoured twelve names. These were collected, counted by scrutineers, and reported without a murmur of dissatisfaction, because it was not only fair, but the only fair way of conducting such an election.—A. D., Kingston.

#### THE N.C.S. ANNUAL MEETING.

It affords me great pleasure to learn that the correspondence which has recently appeared in the *Journal of Horticulture* anent the above Society has resulted in an addition to its number of members, and thereby given it strength. When I first brought the matter of its certificates to the notice of your readers I had no other wish but to strengthen the Society. With your permission, I will still continue such letters; further, will you let me add, when the "Beauty of Exmouth" correspondence is finished, I propose publishing the whole in book form and to distribute it among the Chrysanthemum fraternity generally, and I expect the Committee of the N.C.S. will award me one of the Society's very best medals for the great assistance I have given.

Many members have written me asking why I did not attend the annual meeting and demand a thorough investigation into the Beauty of Exmouth case. To such let me reply that when I learn the Committee are desirous of an unbiased investigation I shall only be too pleased to meet them. To journey about 400 miles only to be "sat on" or talked down is a "pleasure" and expense I care not to indulge in. However, I have carefully read the Secretary's annual report, and if not occupying too much space should like to offer a few remarks on it. Can Mr. Dean or any other official inform us why one particular name in connection with the Holmes Memorial challenge cups is given such prominence? Did the bearer of that name collect the whole of the money subscribed for the cups? If so, he certainly deserves a word of praise, and other matters will explain themselves.

There were certainly just as important subjects omitted from the report—to wit, the "Wells" case, and how a member of the Committee

had been condemned for his action in the affair. Neither is there anything said about the Beauty of Exmouth case, the appointment of an "Investigation Committee," the result of the "investigation," and how a "lawyer was consulted," &c. Surely these matters are as important to the Society as the name of the member who initiated the Holmes' Memorial cups.

The next annual report should contain several interesting items. For example, "At the last annual meeting a new rule was proposed by Mr. Addison for the purpose of punishing offenders; but the Secretary informed the meeting that if such rule was adopted he should resign his position as Secretary. Also, that when several gentlemen were proposed as members of the Committee attention was called to the fact that they had taken part in a controversy criticising the management of the Society." But what curious reasoning some of the officials display! These members had taken part in a discussion which had benefited the Society by adding to its number of members. One of your contemporaries comments on the fact that only Mr. Addison and Mr. Wells spoke in favour of the proposed new rule, which stipulates that any member found guilty of any irregularity should be expelled. If we may judge how Messrs. Pearson's, Goodacre, and others' names were received, it would only be fair to infer that any committeeman who supported such rule against the wish of certain officials would be a marked man. I can only say that I have received letters from many of the Committee in favour of such rule, and also favouring a thorough investigation into the Beauty of Exmouth case; but they dare not speak, so it appears.—W. J. GODFREY, Exmouth, Devon.

[We have another trenchant letter on this subject, for which we cannot possibly find room this week.]

#### CHRYSANTHEMUM MRS. JACOBS.

THIS variety is deserving of more extended commendation than it has hitherto received. At Bradford, York, and Hull it obtained certificates and attracted a large share of attention from the visitors. To those who do not look to mere size in a flower as its chief qualification, Madame Baeo, from which Mrs. Jacobs is a sport, has always been highly appreciated for exhibition purposes; but where medium-sized flowers for decoration purposes are required it has held a high place, and the sport when it becomes known will be an acquisition for either purpose on account of its popular colour, which may be best described as a warm terra cotta softened to a rosy fawn, difficult to describe but most beautiful in appearance.—KIWI.

#### JUDGING CUT BLOOMS—BY COMPARISON.

I HAVE many times been a witness of the various methods adopted by judges in arriving at their decisions regarding the relative merits of the stands of blooms in competition. That which I regard as being the least satisfactory is placing a stand of blooms in front of the opposing stand for examination as follows:—The top bloom in the left hand corner of one stand is compared with the flower occupying a similar position in the other stand, and so on until all are examined in the same manner. The number of points which one row is supposed to obtain over the opposing row is added to or taken off, as the case may be. When the same variety is met with in the two stands their relative merits are found and compared. But when can two stands of even twelve blooms be found to coincide so exactly all through?

Suppose a well developed bloom of Avalanche came in comparison with an exceedingly good one of Stanstead White, although Avalanche was in the opposing stand, also the latter, owing to the difficulty experienced in obtaining, it would score two points over its rival, as the former can be grown so much more easily. Again, suppose the same three blooms in the first stand, A, were Vivian Morel, W. W. Coles, and Avalanche, and in a similar position, in stand B, Etoile de Lyon, E. Molyneux, and Elaine. Presuming the blooms in stand A were superior to those in stand B, three points would be scored by stand A. But if in stand B the same varieties were found as named in stand A, and of much superior merit individually, and they were compelled to compete with, for instance, Boule d'Or, Stanstead White, and Mrs. Alpheus Hardy, although of superior quality to those of the same name in the opposing stand, they would be outclassed by reason of the difficulty experienced in producing the blooms of these sorts. In my opinion justice would not be done to blooms so placed, and I know that the plan of searching for the same varieties in the two stands for just comparison is not the general practice.

From a close observation of methods adopted by various judges I think there is but one way to arrive at a just estimate of each bloom, and that is by determining beforehand upon a maximum number of points and allotting them accordingly. I would, in conclusion, suggest to adjudicators who adopt the practice and method I condemn to consider the matter well between now and the next show season, and see if my remarks are not justified.—SADOC.

#### CHRYSANTHEMUMS AS ANNUALS.

I HOPE I shall not surprise the growers of large blooms for exhibition by adopting such a title to my paper, or that others will not think that I am furthering the interest of those firms who offer prizes for plants grown from seed purchased direct from them. The apparent ease with which Chrysanthemum seed can now be purchased, and the large amount of interest to be gained by trying the experiment, alone prompts me to pen this short article.

During the early part of last year I tried the experiment by sowing

some seed. In a few days the young plants appeared, after the manner of Mustard and Cress. When large enough to handle they were pricked off into boxes similar to Lobelias; then in order to try and avoid the large number of suckers that seedling Chrysanthemums are always throwing up from their base, when they were tall enough, say from 1½ to 2 inches, I cut them all off at the surface of the ground with a sharp knife, inserted the tops, and treated them as cuttings. All readily rooted in a propagating pit, and from that state they were placed singly in pots the same as other Chrysanthemum cuttings are treated, repotting as it became necessary. The great variation in foliage and the marked difference in habit afforded me much interest to watch them on summer evenings.

During August, finding that they were somewhat late in showing their bloom buds, I became impatient and pinched out the tops of many plants. This had the result of producing several breaks; of these I selected five or six of the strongest on each plant, and allowed them to grow and bloom without further manipulation. The major part of them either proved singles or semi-singles; some resembled the Pompons, while a few favoured the Japanese and incurved varieties. The singles were remarkably pretty. One was like the yellow Marguerite, while another was very similar to the Ox-eyed Daisy, *C. Leucanthemum* (in all but foliage). A very large per-centage of them were highly pleasing and interesting, and would be useful in most gardens where a stock of flowers are required late in year.

Chrysanthemums grown thus would be very suitable for standing about in corridors, or for fringing or mixing with groups. Ladies, as a rule, are very partial to single flowers, and I am sure from my own results it would be worth repeating annually, for after flowering all could be consigned to the rubbish heap, having performed their part exactly in the same way as Cinerarias are treated. To all that can afford the time for growing seedlings let them try the experiment, and I can assure them that the results will amply repay the time spent upon them.—J. W. MOORMAN.

### A PRIMER ON HORTICULTURE.

MESSRS. MACMILLAN & Co., the well-known London publishers, issue shilling primers on various scientific and practical subjects. The latest edition is entitled "HORTICULTURE," and consists of ten lectures delivered by Mr. J. Wright and coadjutors for the Surrey County Council. Though necessarily much condensed, the lectures cover a wide field in cultivation, about 140 subjects being included in the list of contents. The lectures are entitled—1, "The Advantages of Allotments and High Culture of the Land." 2, "The Soil: its Nature, Preparation, and Improvement." 3, "Raising Crops, Trees, and Plants." 4, "The Food of Crops—Manuring the Soil." 5, "Enemies of Crops and Trees." 6, "Planting Vegetables and Fruit." 7, "Profitable Culture—Green Crops and Small Fruits." 8, "Profitable Culture—Root Crops, Fruit Trees, Tomatoes, and Mushrooms." 9, "The Preservation and Disposal of Garden Produce." 10, "Encouragement and Endeavour—High Ideals in Gardening."

As a sample, we cite the concluding portion of the first lecture, with a few of the questions and answers arising therefrom.

What may be termed the garden culture of fruit and choice vegetable crops for sale cannot be successfully conducted in small field plots in remote country districts, far distant from railways in direct communication with great centres of population; but such crops can be grown much better than they are now in gardens attached to homesteads. Families may have better supplies than heretofore of what is wholesome and delicious, while those

FIG. 36.—RAISING AND BLANCHING SEAKALE.

a, Root cutting made in the autumn; b, showing buds in the spring; c, rooted and growing, side buds marked for removal; d, rooting and producing leaves; e, root and crown with leaves removed in the autumn ready for forcing or covering with soil; f, growth from the crown ready for cutting and use.

who are gardenless in the localities and adjacent towns will be glad to take the surplus when fresh and of the first quality. It is low quality produce that finds no sale. The best is always in demand at prices which are remunerative to the growers.

Splendid culture is displayed in some field plots, and evidence of taste and loving care is apparent in bright windows and forecourts, as well as in full and well-cropped gardens generally; but these are in the minority, a

minority, however, which is happily becoming less yearly, especially in districts where encouragement has been given to induce a more general indulgence in the healthful and delightful pursuit of domestic gardening.

Our wish is that all shall be taught to make their gardens and pots to the fullest extent useful and enjoyable. We are earnest in this work, and hope to incite earnestness in others, because we know it is for the good of all. We wish to see mutual trust, confidence, and goodwill prevail among all sections of the community, for it is only by a linking together of the best efforts of all that the greatest number of homes can be made happy and the nation prosperous and strong.

FIG. 37.—SEED POTATOES AND RESULTING CROPS.

Prepared set (as in tray) and its crop on the left; weakened set and its crop on the right

### QUESTIONS AND ANSWERS.

Q. How much land can an employed labourer work fairly in his leisure hours?

A. That depends on the land and the man. Heavy land needs twice the labour that light land does; and a man who delights in gardening will do twice the work that another will who takes no pleasure in it. It is better to work twenty rods well than forty badly; or to have a rood clean and fertile than an acre slovenly and exhausted. Those men should have the most land who manage it the best, whether it is apportioned in rods to labourers or acres to farmers, because the one class improves and the other depreciates the value of land.

Q. Do you think a man who is in full and regular employment can manage a rood of land to his advantage in his spare hours?

A. Many do this; but others would be better with half the quantity. A rood (quarter of an acre) of good land well managed will grow from 2 to 3 tons of Potatoes besides some other crops, and the produce must be of advantage to the tillers.

Q. Do you know of any instances of working men having allotments of an acre?

A. Yes; many, and many who have 2 acres managed well, but the men are not in full employment as wage-earners, and are always ready and glad to work when wanted by the farmers of the district.

Q. Do the farmers object to the man having so much land?

A. Not in the least in the district where it has been the custom for many years, because they know they can get men to do their work when the work needs doing.

Q. Are you of opinion that small plots of about 20 rods can be of any real service to working men and give them satisfaction?

A. Decidedly. There are at least 5000 of such plots around Nottingham alone, and so greatly are they valued that if such an impossible thing were to happen as a movement for dispossession it would lead to a provincial revolution.

Q. Can you say what crops are chiefly grown on these plots?

A. It may fairly be said that in one or the other of them everything may be seen in its season that is pleasant to the eye and good for food—flowers of various kinds, fruit trees and bushes in thousands, and vegetables of the best varieties and the highest quality. The gardens are much cherished, and so are thousands of others still smaller in various parts of the country.

Q. What is a fair price to pay for land in allotments?

A. You may as well ask me what is a fair price to pay for a watch. I have one I would rather sell for 10s. than another for £10; and I would much sooner pay at the rate of £5 an acre for the best land than 10s. for the poverty-stricken and inferior.

Q. Do you think that increasing the number of small cultivators will increase the wage-rate of workers on the land?

A. I do not; because it has not done so in parishes where the land has been largely tilled by small cultivators for generations. Where men are content to remain by earning a little in addition to their wages the numbers are apt to increase; where they are not they diminish, and scarcity in anything raises its value, abundance having a contrary tendency. It is not, however, within my province to answer questions of a controversial nature connected with the acquirement and value of land, and I ask that they may be limited to points of cultivation and management during our course of lectures.

The work contains thirty-seven illustrations. Fig. 36 represents the raising and blanching of Seakale by covering the crowns with soil;

fig. 37 shows well prepared and weakened Potato sets with resulting crops.

The Primer will be useful for distribution amongst cottagers and allotment holders, and not less so to young gardeners; also to some who are not very young, as well as to amateurs, while it contains points for dilution by lecturers. Copies can be had from booksellers, not from the author.

NATIONAL ROSE SOCIETY—TEAS IN MIXED CLASSES.

THIS is a subject which is often discussed with bated breath at committees, and referred to in other places as a matter that *must* be set right, but so far I think those who see some grievance in the fact of an unlimited number of Teas being allowed to be shown in the mixed classes have a following which has hitherto been small, and in the future is likely to entirely disappear.

It would in an early year be a very dangerous rule for our Society to enforce the exhibition of nothing but H.P.'s in the mixed classes, and our champion amateur rosarian practically settled the question recently, when he gave it as his decided opinion that it would never do even to limit the proportionate number of Teas an amateur should exhibit in a mixed box, as he might find it difficult to put up forty-eight varieties.

There can be no question that a few Tea Roses lighten up a box made up principally of H.P.s. There can be no contrast so effective as that of a good yellow such as Maréchal Niel or Madame Hoste with reds like Charles Lefebvre, A. K. Williams, or Victor Hugo, and the white Teas also give a refining tone to a mixed box which adds to its beauty without detracting from its merit. Moreover, "J. B." should bear in mind as a sound and experienced judge that no special merit or weight is now attached at any good Rose show to the fact of Teas being in a mixed box, as the Teas must be of a size and finish quite on an equality with the H.P.s shown in the same class.

The only people who are likely to demand or have spoken of such restrictions as "J. B." thinks necessary (and even their cry from being "mezzo-forte" sometime back is now becoming decidedly "piano") are rosarians who hardly grow any Teas. As, however, the culture of Tea Roses is extending rapidly there will before long be very few non-growers of this the most desirable class of all. It would be a bad day for the N.R.S. if they ever place any such restriction as the one now being discussed. It would, as far as I can see, help no one, and it would seriously militate against the effective appearance of our large exhibitors' boxes, which would look most monotonous if only shades of reds and pinks predominated. However, from a recent slight trial of strength on the question, one could see that at present the opinion against "J. B.'s" proposition is overwhelming, and such being the case it is not in the least likely at any time to be carried.—CHARLES J. GRAHAME, *Croydon*.

#### THE NATIONAL ROSE SOCIETY'S METROPOLITAN SHOW.

YOUR correspondent, "W. E." page 131, asks why the Royal Botanic Society has not been approached on the subject of holding the Metropolitan Exhibition there. Now in my previous communication I said that everything had been tried in London for that purpose, and when the break up occurred at South Kensington I was deputed by the Committee to approach this Society, and I may say of all the impracticable bodies I had to do with this was the most so, and after a long consultation with its Secretary, I left, and reported to the Committee that nothing could be done; they would give no subsidy, no privileges to members, and, in fact, would do nothing to meet us; and so this, like many other proposals of a similar character, fell to the ground.—D., *Deal*.

#### "THE ROSE DERBY."

I HAVE no wish to continue this discussion, the weight of argument and the trend of public opinion in general with regard to all societies which call themselves "National" is towards a more national policy than at present prevails. But as my veracity on one point—viz., the length of Mr. Grahame's membership of the N.R.S.—has been challenged by him (he would have us conclude he is a very old hand), and although I have offered to apologise if I am wrong, he has done nothing to explain away the fact that his name does not appear in the lists of members of the N.R.S. for the years 1885, 1886, 1887, and 1888, nor, for aught I know, in any preceding year. It is an easy matter to correct this if it is wrong.

The argument from length of membership taken by itself may be nothing, but becomes something when taken in conjunction with other limitations which have been previously noted, together with the fact (if I am inaccurate he will kindly enumerate other shows) that Mr. Grahame has no personal acquaintance with Rose shows north of the Trent, except in the case of Chester last year.—J. H. P.

#### ROSES v. LILIES.

HIGH treason! The Lily put forward as not inferior to the Rose. And this in the very home of the Queen of Flowers, for it is Dr. Wallace

of Colchester (page 128), where the finest Roses in the world are grown, who raises the standard of revolt. Well, a loyal subject as I hope I am, must needs do battle for the Queen, so forward with all courtesy to the fray.

Fragrance is the first point chosen, to be sure a matter of opinion; but can it seriously be denied that some Lilies at least are unpleasant in odour to most people? And is that true of any Rose? The prevalent opinion I think is that the scent of all bulbous flowers is apt to become disagreeable in a close room or in large quantity, but whoever had too much of the fragrance of a Rose? For lasting as a cut bloom the Lily must have a point, and the Rose can afford it; the Queen does not tarry till you tire of her.

"Under glass you may have Lilies all the year round in bloom, not so Roses." I am astonished. Not at Colchester? then surely elsewhere. I forget which year it was that I gathered a Rose out of doors in Suffolk in each of twelve successive months, but it was duly recorded in the *Journal of Horticulture*. Can Dr. Wallace point to a similar record with Lilies?

"No comparison in grace and stateliness." This, again, must be a matter of opinion; for "high art" or ecclesiastical paintings the formal precision of the Lily is certainly more suited, but this style would by no means be considered the *ne plus ultra* by many.

Dr. Wallace admits the Lily is more difficult to grow, and will not suit so many positions as the Rose, but claims an absence from green fly and caterpillars for his protégé. We will admit these two points as cancelling one another, and indeed I do not blame insects for preferring to feed on Roses rather than Lilies.

The defence is sufficient, I think, and the queen can afford to show her magnanimity by declining to attack in her turn. There is plenty of room for both flowers, and even for enthusiasm on the subject of Lilies without finding fault with the universal homage offered to the Rose. I think (was it not lately shown in the *Journal*?) that the verdict of the poets is plainly and strongly in favour of the generally acknowledged queen. Why, even when Swinburne sings of

"The Lilies and languors of Virtue  
And the Roses and raptures of Vice,"

he chooses and cries aloud (alas!) for the latter.

#### FORMALITY AT ROSE SHOWS.

"W. E." (page 131) complains of formality at Rose shows. He wants informal and graceful masses of decorative and buttonhole Roses, and other changes. To this it must be answered that at Rose shows in general, and at a large part of the Metropolitan Show, the Rose is treated as a florist's flower, and judged according to rules. All informal exhibits, such as bouquets, must be judged according to the individual taste of the Judges, which is less satisfactory to the competitors than acknowledged rules. Why not "the names of the Roses very much *en evidence*?" A large portion of the spectators, as may plainly be seen, take the greatest interest in the names, and it would be a hardship to them if the cards were not legible. I fear they are not so clear as they might be in some cases. Then there *are* classes for garden Roses and for buttonholes; and I am sure the exhibits in the latter class of Mr. Mattock of Headington *are* masses of bloom, and very beautiful. I, too, have called out for "plenty of space;" I wish we may get it. But I cannot think why "W. E." wants "American" prizes.—W. R. RAILLEM.

#### STARVED MUSHROOMS.

IT may seem somewhat of a misnomer to term Mushrooms, growing from a bed of manure, starved, but it is a correct definition in many cases. Manure utterly devoid of moisture offers very little more support to Mushrooms than the poorest dry soil, and not so much as might be derived from the latter after it has been well moistened. When, therefore, a very dry bed produces Mushrooms, these are poor and dry, though no more so than might reasonably be expected from such starvation treatment. Unless the manure can be kept sufficiently moist to be constantly, though very slowly, fermenting and decaying, there is nothing to support the Mushrooms, even though the spawn may have run well. A fairly good first crop may be obtained, then all is over. Instead of this comparative failure it ought to be possible to have one extra heavy first crop, and one or two fairly good successional supplies from each bed. Last November our first bed in a heated house commenced bearing early in November and yielded freely well into December. Since then we had a very acceptable second crop, and a third now showing through the soil promises to be even more satisfactory. The secret of success would appear to be in providing enough, and only just enough, moisture in the bed, and a gentle heat in the house. Of bottom heat, that is to say, inherent heat, there is, nor has been at any time, next to none; the trial sticks, whenever tried, nearly always feeling comparatively cold and moist.

For some time past I have been under the impression that too much importance is attached to having a strong heat in the bed when spawned. Doubtless the spawn runs the most freely in a temperature of 85° or so, and experts advise spawning when the heat has declined to that figure, though some recommend 90° "with a downward tendency." Supposing the manure has been well prepared, and the bed formed when the manure is in both a sweet and semi-dry state, the heat recommended for spawning is safe enough as a rule; but all the same it would have been better that such high figures had never been reached. These high

temperatures quickly get rid of what little moisture there is in the manure, and this is the commencement of the starvation process. Where the plan of daily syringing the beds, walls, and floors prevails it is no uncommon occurrence for the surface of the beds to be too moist while the manure underneath is quite dry. As fast as the tiny Mushrooms peep through the soil most of them change to a dirty brown colour, become soft, and make no further progress. Instead of the syringe being used daily in the Mushroom house under my charge it is never employed at all, the watering pot, and that only for thoroughly re-moistening an exhausted bed, being what we believe in. Very fresh manure ought not to be principally used in forming fresh beds. Much of ours is not less than a month, and not unfrequently some of it six weeks, old by the time it has been prepared for use, and rarely indeed does the heat rise to 90°. More often than not the maximum would be 85°, and then for a short time only. Being somewhat stale or well advanced in decay rather deeper beds may safely be formed than is usually done. The best I have ever had, or indeed ever saw, was 18 inches deep at the back and 15 inches deep in front, and within a week of its being spawned the trial sticks were scarcely warm. No attempt was made to hurry this bed, and no water was given, but in the course of about two months enormous masses of fine succulent Mushrooms were to be seen all over the surface. So much for being content to "let well enough alone."

A mulch of strawy litter serves to conserve a considerable amount of moisture in a bed, and is to be commended accordingly, but that alone will not suffice to bring up a second crop. As I have previously hinted there ought, either with or without the aid of a mulch, to be enough moisture in a bed to start and sustain a first heavy crop without any being supplied from the surface. If there is not a partial failure is imminent. After the first crop has been cleared off, the old stumps with the mass of solid matter attached being duly scooped off according as the Mushrooms were pulled, and the holes refilled with fresh soil, about a week or ten days may well elapse, and then a thorough soaking of water should be given. Nothing but quite warm soft water ought to be used at first, this being applied through a fine rose, and repeated the following day. Even then the chances are the manure will not be really well moistened, but it will be in a better state for receiving liquid manure, or say a supply of either Thomson's or Bentley's Vine border manure. Nitrate of soda and common salt are also of good assistance in bringing up a second heavy crop of Mushrooms, about an ounce of either of the four kinds named being dissolved in every gallon of well warmed soft water, and then applied through a fine-rose pot. This application following upon the waterings given should provide enough moisture and food to support the second crop, and the process may well be subsequently repeated with a view to bringing up yet another crop.

A too free use of fire heat is very detrimental to Mushrooms, and should be dispensed with as much as possible. If there is a constant demand for them, then must a little warmth be given all the while, but at no time ought a temperature of 55° to be exceeded, from 45° to 50° being quite high enough as a rule. The fire heat invariably accelerates fermentation in the beds, and they dry all the more rapidly accordingly, poor starved Mushrooms being the result. Where the beds have overheated the manure assumes a musty dry state, which nothing that can be done afterwards will render fit for the production of Mushrooms. Another extreme has also to be guarded against. When the manure is in a cold, saturated state the bed cannot be made productive. It is the happy medium that brings maximum crops.—W. IGGULDEN.

#### A PLEA FOR HEPATICAS.

How seldom do we find a really good collection of these early spring flowers cultivated! In many gardens they may be classed among neglected plants. One sometimes meets with a few grand clumps in very old gardens, or a solitary plant may occasionally be seen in front of a wayside cottage.

With me they have always been especial favourites, and I think they are quite unrivalled among hardy herbaceous plants which flower during February and March. Nearly all the varieties I have seen succeed the best in a rich but rather light soil. If planted in positions where they obtain shelter from the north and north-east winds, the flowers are produced as early as Snowdrops grown under the same conditions. Should the weather prove wet and unfavourable at flowering time, the precaution of placing a handlight over the best clumps is well repaid, especially if the flowers are wanted for use in a cut state. When this course is pursued the flowers are kept perfectly clean, come better in colour, and the stems are considerably lengthened, a combination of advantages well worthy of the extra trouble involved in producing. Where large masses are wanted the clumps should be left undisturbed for several years.

When it is necessary to increase the stock clumps may be divided into pieces having three or four good crowns each. If this is done in October, the divisions being placed in good soil, and afterwards receive proper attention in the way of frequent stirrings of the soil during the summer months, and in dry weather are given a few good soakings of liquid manure, extra fine flowers are produced the following year.

*H. angulosa* is, perhaps, the most showy variety grown, and produces very large flowers of a sky blue colour. *H. triloba alba* and *triloba cœrulea* are also good, and showy single varieties of the smaller flowering type, but I think the most useful among this class is *triloba rubra*, because it blooms very freely, and supplies a colour so much wanted in hardy flowers at the present season—viz., deep red. There is also a double form

of this variety, which is perhaps the best known of all Hepaticas. A double blue form also exists, but being a somewhat weak grower it is not plentiful.—H. DUNKIN.

#### URCEOCHARIS CLIBRANI.

WHEN a few flowers of this interesting hybrid were exhibited, under the name of *Eucharis Clibrani*, at a meeting of the Royal Horticultural Society last year by Messrs. W. Clibran & Sons, Oldfield Nurseries, Altrincham, a doubt as to what should be the correct designation of the plant was expressed. The raisers inform us that the plant is the result of a cross between *Eucharis grandiflora* (better known as *E. amazonica*) and *Urceolina pendula*, and on the suggestion of Dr. M. T. Masters, F.R.S., it has been named *Urceocharis Clibrani*.

The character of the flower will be seen by referring to the engraving

FIG. 38.—URCEOCHARIS CLIBRANI.

(fig. 38) which has been prepared from a small specimen sent to us by Messrs. Clibran. The individual flowers, as will be noted, bear a resemblance to both parents. They are borne in umbels on strong stalks similar to the *Eucharis*, and, unlike the *Urceolina*, are erect on first expanding, drooping slightly when past their best. Being pure white and extremely beautiful in appearance, the flowers will prove invaluable for decorative purposes, and when a stock of the plant has been prepared it will, no doubt, be extensively grown. The leaves are broad and as vigorous as those of the *Eucharis*.

#### BRUSSELS SPROUTS.

At the beginning of the second paragraph of the paper on this vegetable, page 135 (*Journal of Horticulture*, February 16th), your correspondent writes, "I cannot understand why it is advised that

Brussels Sprouts should be sown in a frame. Plants raised under glass never have the same hardy constitution that those have raised in the open ground." Having indicated in a previous article that personal experience led me to adopt the frame system of raising seedlings is no reason why others should invariably resort to the same practice. A good rule for cultivators to follow is to base their systems of procedure on the various conditions with which they may have to deal, more especially as regards the climate and soil of their respective districts.

No one who is usually successful in securing satisfactory crops of Brussels Sprouts from plants raised in the open ground will give heed to anything that may be written in support of raising seedlings under glass; but, on the contrary, if failures occur occasionally from climatic causes they might possibly do worse. I may make the remark here that two plantations now occupying the same quarter, and raised under the different systems indicated, present a striking contrast. While those sown in the open, as soon as weather would permit last spring, have been practically a failure, those raised under glass and thoroughly hardened afterwards could scarcely have yielded a finer and more abundant crop, and their green sturdy appearance after such a rigorous winter is surely a sufficient guarantee of their hardiness. Similar results have also been noted in other gardens in the case of frame-raised plants. It would be interesting as well as instructive to know the actual temperature Brussels Sprouts should be able to withstand without injury before they could be said to possess what your correspondent considers a hardy constitution.

Regarding the question of sowing seed of Brussels Sprouts in the open in February, as practised by your correspondent, the teachings of meteorological records in this district (Ayrshire) makes the raising of seedlings under glass a necessity. Plantations from which adequate supplies of good firm sprouts are obtained here must be finally planted out not later than the 15th May, but how plants sown in the open for this purpose can make headway with the thermometer ranging from 12° to 20° of frost for a week at a time after germination should have been apparent, together with months of bleak east winds prevailing almost constantly, I have not yet proved. For this reason I adhere to a system by which protection is at immediate command when severe weather extremes have to be contended with.—BRASSICA.

### TRIUMPHS AND TROUBLES WITH PEACHES.

A SHORT time ago, no matter how, no matter where, fate brought me into conflict with a Gooseberry grower on the question of pruning the bushes. Having comfortably demolished one another, each, doubtless, deriving considerable satisfaction from the manner in which he had wrecked the other's arguments, we drifted into conversation, and the then stranger, who subsequently proved to be Mr. Reed, gardener to Edward Pettitt, Esq., Broadwater, Oatlands Park, near Walton, clinched the matter by extending, in honest English fashion, a hearty invitation to go and see him as soon as an opportunity arose. That is the way to end a controversy. No bitterness, no recriminations, but just a wholesome hand-shake and an invitation given in the best spirit, and accepted with equal readiness and pleasure. Though personally unknown to me until that time Mr. Reed's name was familiar as a successful exhibitor of fruit at leading Shows, such as the Crystal Palace, and of Chrysanthemums at Kingston, Weybridge, and elsewhere. Moreover, information had reached me of his special success with Peaches. To Walton I therefore betook me. The road was a familiar one, for Broadwater is the next place to Duncevan, rich with the Rhododendron and other treasures collected by the kind-souled James McIntosh, now gone, ripe in years and honours, to his rest. Memories of bright days in the beautiful garden of this noble old English gentleman, and of hours beguiled by his genial and kindly wisdom when his health permitted him to play the part of guide and host, are inevitably recalled when Oatlands Park is revisited.

It is a little too early in the year for the full beauty of the locality to be recognised; but late in spring there are few among the many delightful districts which are to be found in Surrey by all who know how to set about the search to exceed Oatlands Park in attractiveness. Duncevan, Broadwater, and other residences near stand on the very brink of the steep descent into the Thames Valley, and consequently the pleasure grounds slope somewhat abruptly down. I should like to pause and speak of them; but Peaches do not grow there, and so I must pass on. A brief tribute should, however, be paid to the taste and skill with which the garden has been managed, for shrubs and trees have been arranged in a manner appropriate to the configuration of the ground, and through cunningly contrived breaks and depressions pleasant glimpses of the glistening water can be obtained. Under glass the handiwork speaks for itself. There is a bright display of flowering and foliage plants, together with many Orchids, all healthy, clean, and happy.

Beyond doubt it is in the fruit department that Mr. Reed excels. The collection of Apples, Pears, Plums, Cherries, and bush fruits is large, varied, and splendidly managed. At a future date I hope to say something about them, but at present attention must be restricted to the Peaches. There are two houses, the trees in the early one now being in bloom. In both the condition of the trees repays the closest inspection. They are models of health, vigour, and skilful training. The rule followed is to remove all fruiting wood immediately the Peaches have been gathered, and in the case of only two trees was it departed from last season. The difference between these and the remainder is very marked. The summer pruned trees are furnished with as fine a frame-

work of fruiting wood as it has ever been my fortune to see. Many of the shoots are 18 inches and 2 feet long. "Gross!" someone may ejaculate. Not at all. The wood is stout, firm, with the deep brownish tint denoting perfect maturity and studded with huge plump buds, or, in the case of the early house, wreathed in fine, substantial, perfectly developed blossoms. True it is that long shoots do not always mean fine fruits, but when as stiff and well ripened as those at Broadwater they bespeak no mediocre crop. The late house is 87 feet long, the front border 5 feet wide, and the back 2 feet. Last year 1600 fruits were gathered from the structure. The knife has been used with so much judgment and boldness that the trees, save for the mere skeleton of the framework, are entirely furnished with fruitful wood, and by adherence to the summer pruning of the fruiting shoots a succession of magnificent wood is secured. In the two trees not so treated the wood is distinctly stunted as compared with the others, and a lesson is afforded of the results accruing when Peaches are intelligently managed.

In feeding his trees Mr. Reed follows lines not generally adopted. As soon as the fruit is gathered three barrowloads of dried fowl manure are spread on the borders in each house. The material is spread to dry when collected, and pointed very lightly into the borders. If wet the amount of ammonia arising would probably injure the leaves. This application lasts them until spring, when a dressing of wood ashes is applied to the borders, also to the vineries. The potash helps the fruit wonderfully at and after stoning time, and aids materially in the production of fine examples. The use of fowl manure offers a useful hint to other cultivators of Peaches. Few recognise the value of this fertiliser, which analysis shows to be far superior to animal manure. A ton of fowl manure yields 24 lbs. of potash, 41 lbs. of phosphoric acid, 87 lbs. of nitrogen, and 47 lbs. of lime, a total of 199 lbs., as against 66 lbs., the product of pig manure, which is in its turn richer than the excrements of horses and cows. Theoretically we learn from these figures that the gatherings of the fowl houses compose one of the gardener's best assistants, and the Broadwater Peaches drive home the theory in as practical a manner as could be done anywhere in the kingdom. It is to be hoped that cultivators may learn to appreciate the manure at its true worth, and make better use of it than is now often done.

I turn from the triumphs with Peaches at Broadwater—and a triumph their culture undoubtedly is—to a word as to the trials, or rather to a trial which for a time played sad havoc with the worthy gardener's peace of mind. He loves his trees, and devotes close personal attention to them. They are his delight and his pride. Conceive then of the blow that befel him when an unhappy error on the part of a junior while he was away for a holiday destroyed nearly a whole houseful. They were thoughtlessly dressed with undiluted oil, and when Mr. Reed returned home the sight when he entered the house nearly broke his heart. Like a wise man he went home to talk over the catastrophe with his wife, but her consolations did not suffice to bring peace to his troubled mind. "I hadn't a wink of sleep that night," said Mr. Reed to me, with the look of a man whose thoughts revive some sad experience. "I tossed and turned trying to think out what to do." Something was done, and done promptly. He hied him to Chelsea, and told his story to the head of the great firm there, whose sympathies, ever quick to act when gardeners or gardening are concerned, were at once aroused. Some of the finest trees from the Southfields stock were sent off. They were planted on the 11th of March, and from eight of them sixteen dozen fruits were gathered the same season, so after all the trial was turned into another triumph. Then Mr. Reed went on to tell what happened when the bill—and he speaks gratefully of the consideration for the untoward circumstance which its dimensions bespoke—came in. He was anxious to take the responsibility upon himself, not liking the idea of a good employer suffering for such a mishap, but the latter generously refused to allow it. So the trial was met, the gardener's serenity restored, and his respect for an appreciative master increased. Once more the Broadwater houses are full of healthy trees, a source of gratification and pleasure to Mr. Pettitt, of pardonable pride to his gardener, and of instruction to visitors.—W. P. WRIGHT.

### AN ELEVATED GARDEN.

RELATIVE to the surrounding ground level there are perhaps few gardens in the kingdom that are more up in the clouds than is the parterre garden that is found on the summit of the castle keep at Farnham, when that elevation is reached. The entire keep, enclosed by a stone wall of some 7 or 8 feet in thickness, seems to stand on an acre of ground. The wall reaches to a height from the lawn beneath it of some 50 feet, and is scaled on the north side by a series of stone steps, somewhat zig-zag in form. The walls up which this ascent is made are covered with wonderful masses of Ivy and Clematis flammula, and on one side of the steps is a perfect wall of Cotoneaster. The whole of the external wall is thus picturesquely dressed or draped with hardy foliage and climbers, whilst on the top are many trees of considerable size, which it is needful to prune occasionally as the wind force so high up is very great.

On the top what was, in the days of the previous Bishop of Winchester, a vegetable garden, has been converted into a sunken flower garden, nearly half an acre in extent. Inside the wall at the top runs a raised gravel walk, and the flower garden lies some 3 feet lower. It has a turf floor with two broad cross walks. Beds of Roses, herbaceous perennials, and annuals beautify it in the summer. Every piece of turf and particle of gravel as well as manure has to be hauled up by a rope to the great height from below, and it is no wonder if the work of

renovation proceeded slowly. Mr. Dowding is entitled to all praise for his perseverance under such difficulties. Water is now laid on, being supplied from a distant elevation near Caesar's camp. No wonder that apart from the garden, which must be very delightful in the summer, the look out should be a great attraction, for the views are very extensive, and embrace the whole of the surrounding country.—A. D.

## WATER.

DOUBTLESS it has often been a matter of surprise to many persons besides myself that proprietors of large establishments will go to a great expense in building and keeping up fruit houses, and that not one in a hundred will make provision for an adequate supply and the economical distribution of that greatest of all necessities in a horticultural establishment—water.

In some places, no doubt, it is a difficult matter, but in the majority of them it is an extremely simple one, and I may, perhaps, simplify it a little more by saying at the outset that you must not despise spring or hard water if that is the easiest to obtain. It will do no harm to the roots of fruit trees and may possibly do them a great deal of good. I prefer it to rain water. When I first took charge of a large garden for a nobleman I found several acres of water close at hand, but comparatively none in the garden. A horse and cart and several men were employed a good part of the summer carrying this necessity. Of course the supply was very insufficient, and it always is under such conditions. As the water was on a lower level than the garden a hydraulic ram was suggested. "Shall I be £5 a year the better off in the way of produce or expenditure?" asked my employer. I could only say I hoped so, and that failure in some respects was inevitable without a proper supply of water. Well, the hydraulic ram was fixed for the sum of £120, and it gave us an ample supply of water for all purposes. It is a recognised fact that some of the products were better than they had ever been before in that garden, and I am positive that the improvement could not have been made without the water. Now, here was a garden costing over a thousand pounds a year, and yet the few pounds that would give an ample supply of water, lessen the drudgery and worry and prevent some of the failures, had been withheld for ages.

Having got the water is a great point gained, but this is not all. It has to be distributed, and must be done in a proper condition and in an efficient manner. I maintain that the watering of inside fruit borders is such an important operation that it should never be done by any but the most trustworthy hands. You may teach a labourer to thin Grapes, disbud Peach trees, ventilate houses, crock pots, and even to do that equally important work, the stoking, because you can see at a glance whether any of these operations are properly done; but in watering, especially with the hose, he is apt to make mistakes, and the errors so made are not readily detected. Somehow the corners and ends of borders are apt to be partially neglected, and these parts, especially where there is masonry, have a habit of getting dry the quickest. Personally I seldom trust the watering of such borders to anyone but myself. Having seen that the application of water is such an important matter, it shows the necessity of making provisions for supplying it as fast as the borders can take it. If a man's time is worth a shilling an hour, he should not be allowed to waste it by holding a hose which discharges water only at the rate of 3 or 4 gallons a minute.

My present arrangements for watering, although not perfect, are better than many. The source of supply is a spring which never fails or diminishes, and is situated at a suitable altitude. A large tub holding 3600 gallons, obtained cheaply at a sale of brewery stock, is sunk in the side of the hill for storage. This is connected with all the houses by means of pipes and taps to which a hose can be fixed. In the summer time, or as soon in the spring as the water in the tub reaches a temperature of 55°, it is used direct from there. In the early spring we have arrangements for warming it, which I will attempt to describe. A little below the tub is a cistern capable of holding 400 gallons. By means of a branch pipe and tap this can be filled from the tub, and when warm the supply from the tub can be shut off and the warm water drawn in any of the houses from the cistern by the same arrangement of pipes as when it is drawn from the large tub.

For warming the water we have a small boiler fixed slightly lower than the cistern and at one end of it. The connection is made by two short lengths of 1½-inch pipe, one of these rising from the top of the boiler to act as a flow, and the return pipe enters near the bottom. The two pipes merely enter the cistern one above the other, and are open to it, so that the boiler is self-filling and can never be empty, although the cistern might run dry. We had at first one of the small upright drum-shaped boilers. This answered very well for a time, and heated the water rapidly; but the

water space being very small the sediment from the constantly changing spring water blocked it, and it burned through in two years. What we have now is a common bell-shaped laundry boiler with a lid fixed to it. It does not heat so rapidly as the former boiler, but it does the work well enough, and it has been in use five or six years.—WM. TAYLOR.

## DISCUSSION ON APPLES.

### APPLE SYNONYMS.

THERE is a mistake in my note on page 161 last week. I did not intend to suggest anything more than sending fruit, leaves, and wood of Dr. Harvey, Wormsley Pippin, and Waltham Abbey Seedling for showing they are one and the same variety. The name of Golden Noble was inserted accidentally. I think the Fruit Committee in "British Apples" (page 376), 1888, wrong in stating that Golden Noble and Waltham Abbey Seedling are identical.—JOHN CHINNERY, *The Gardens, Downton Castle*.

### APPLE WORMSLEY PIPPIN.

IN a garden I was recently looking through I found Waltham Abbey Seedling grown as Wormsley Pippin, and the variety having the first appellation was something quite dissimilar and of no special merit. No doubt we may admit that Waltham Abbey Seedling is grown also under the names of Wormsley Pippin and Dr. Harvey, and the only remaining point to clear up is which name has prior claim. In any case one recognised title is enough. With respect to Mr. Chinnery's statement as to Golden Noble and Waltham Abbey Seedling at the Apple Conference of 1888 being pronounced identical, I would point out what was really done. Golden Noble was shown under both appellations, and they were pronounced identical. No body of persons ever yet described genuine fruits of the two sorts as being identical.—A. D.

### COOKING TEST FOR QUALITY.

THIS is a very interesting subject, and I hope there will be some comments on "W. B.'s" class list (page 130), or that others will relate their experiments. *De gustibus non est disputandum*, but surely it is odd that such very differently flavoured Apples as Blenheim Orange and Normanton Wondon (Wellington) should be in the same class, and that Lord Derby and Sturmer Pippin occupy the lowest place of all for flavour.—W. R. RAILLEM.

## FRUIT BLOSSOM.

THE last year's growths, twigs, and spurs of Apricot trees are studded with blossom buds ready for expanding, and the time for affording protection is at hand. Pears have the most blossom buds, bold and promising on the first-formed spurs on the two-year-old wood. Young trees, or those extending, have by far the grandest display of buds. Restricted trees show many blossom buds so close together, and so variable in size, as to suggest a liberal thinning. This is easily done by dividing them into three sizes—the small, medium, and large, removing all the first, most of the second, and retaining the large bold buds. If there be sufficient of the latter for leaving evenly over the tree at a handbreadth apart, all the other buds may be rubbed off, for there are five times too many for insuring a good set and fine fruit. Where the trees on the Pear stock are closely pruned there is only a sprinkling of blossom buds on spurs from wood over four years old. Such trees grow fine shoots to be cut away in summer, these often producing the sole crop. Some trees have last year's growth terminated by bold blossom buds, and such branches must be cut back to wood buds if an extension of growth is needed.

Cherry trees are clustered all over with buds, and half may be removed with advantage. Some trees produce nothing but blossoms and leaves year after year. Thinning the blossom prevents the trees expending all their energies on beautiful abortions.

Plum blossom promises to be abundant, especially on young trees with the branches thinly disposed. Peach trees have plenty of blossom buds just moving, but they will not take any harm until the pink or crimson petals have burst the integuments that hitherto have protected them. All the trees are not alike promising. Some strong-growing sorts do not mature the wood sufficiently for setting good crops. None has done better than Dr. Hogg Peach in the past, and it is more favourable for fruit production this year than any other variety on a hundred yards run of south wall.

Our national fruit, the Apple, especially the early varieties, give great promise of blossom on garden trees, all on the English Paradise stocks, while many trees in orchards teem with fertility. What we wish to see are clean, healthy, open trees in fertile soil, for these produce the boldest blossoms and the finest fruit. Overcrowding is fatal to productiveness. This Shakespeare knew, or he would not have written

"All superfluous branches  
We lop away, that bearing boughs may live."

Let his words be remembered. On another occasion I will describe methods of protecting the blossoms of fruit trees.—G. ABBEY.

PERHAPS it is too early in the season to say much about the fruit prospects of 1893, but to judge from the appearance of the trees in this district there is every indication of there being good crops if the weather

should prove favourable during the time they are in flower. The mild weather of the last few weeks has brought forward the buds of Apples, Pears, and other fruits very rapidly—perhaps too much so for the season—and they may have to suffer for it later on if we have a spell of severe weather with cold east winds during the time the flowers are setting. I went round and inspected most of the fruit trees in the gardens here to-day (February 23rd) and found them bristling with flower buds from base to top, strong, plump, and considerably advanced for this early date.

The buds of Pear trees trained on south walls are almost ready to burst into flower, and as a slight protection against frost I had them covered with old fishing nets. The pyramid Pear trees in the open quarters are not so easily protected when 30 feet high, so they must take their chance. Pitmaston Duchess I never saw so studded with flower buds all over and so forward at the present time. It makes a beautiful pyramid on the free stock, has a strong constitution, and fruits freely here planted in different positions. But the fruits are so large and heavy that the trees require propping to keep the branches from being swayed about with the wind and shaking the fruits off. Notwithstanding the great height of the trees, many of them bear so low that the fruits are sometimes resting on the ground. Glou Morceau is a late variety, and not quite so forward in bud as the former. It has a pendulous habit of growth, and succeeds well as a pyramid in this locality, and the fruits are not easily blown off the trees. Williams' Bon Chrétien (a

flower buds this year as usual, but there is plenty if the weather should prove favourable to produce a good crop.

Gooseberry and Currant bushes are almost green, and promise an abundant crop.—A. PETTIGREW, *Cardiff*.

It is yet the end of February and the scales have fallen from the blossom buds of Pears in the Thames Valley, and the buds on early flowering trees have a whitened aspect. Such development is sufficient to create alarm. Well may we be thankful for some recent cold days, but there seems to be little prospect of any material check, as the weather continues if not particularly mild, at least moist and open. It may be that so long as the flowers are kept from expanding until the end of April, and that is always warm enough even for Pears, no great harm may be done; but all the same, every fruit grower knows that early starting of the buds, and then because of ungenial weather and low temperature very prolonged expanding, is weakening and greatly militates against fertility. It is a case in which human agency, however skilled, can do nothing.

What we see, especially on Pears, is a superb promise, as the trees generally are thickly studded with blossom buds. The crop last year was a moderate one, and there is good reason to hope, should no harm result from ungenerous spring weather, that we shall have a fine Pear season.

Apple trees, too, are on the whole well set with buds, though many

FIG. 39.—MANGOLD WURTZEL TRAPS FOR WOODLICE AND MILLIPEDES.

A, wood-louse (*Oniscus asellus*), full size; B, pill-millipede (*Armadillo vulgaris*), rolled up as a ball; C, snake millipede (*Julus pulchellus*), magnified, *a* natural size; D, upper half of Mangold; E, lower half of Mangold; F, woodlice feeding on hollow part of Mangold.

great favourite) is so straggly in its growth that it does not make a good pyramid, even with the best of treatment. The buds are prominent, and if this mild weather last much longer it will soon be in flower. It crops well in this district, both on walls and in the open quarters of the garden; but, like the Jargonelle, the fruits soon decay after they are ripe. Beurré d'Amanlis, Marie Louise, Beurré Magnifique, and Louise Bonne of Jersey are looking well and full of bud. These varieties make good pyramidal trees, and fruit freely, with the exception of Marie Louise, which is rather uncertain some seasons. Beurré d'Amanlis is a sure bearer, robust in constitution, and is one of the best kinds I know for renovating inferior varieties, or varieties that are too tender to succeed in the open by grafting them with it. We had a row of very fine pyramidal trees of Easter Beurré growing in a border by the side of one of the principal walks in the kitchen garden here. They bore well enough, but never ripened their fruits satisfactorily, so I had them headed down, or rather the branches shortened back to within a foot or more of the main stem to form a framework for the grafts, and as many as thirty or forty scions of Beurré d'Amanlis were put on to each tree. It is only two years since they were worked, and now they are well furnished, and have all the appearance of established trees from sixteen to seventeen years old, showing plenty of fruit buds. Last year I had some large pyramid trees of Bergamotte Esperin cut back in the same way, and grafted with Beurré d'Amanlis, which will soon make well furnished trees.

Apple trees are clean and healthy and better furnished with fruit buds than ever I remember seeing them. The buds are swelling fast, and some of the earliest varieties are beginning to open and show a tinge of red on the top. The trees of Cox's Orange Pippin, Blenheim Orange, Eeklinville Seedling, Lord Suffield, Wellington, Annie Elizabeth, Beauty of Hants, and Golden Noble could not look better than they do at present, but a hard night's frost might blight the best of prospects with the buds so far advanced at this early date.

Peach trees are covered with strong healthy flower buds which are almost ready to burst into blossom with the first few hours' sunshine. The walls here have a broad stone coping which project some 9 or 10 inches over with iron hooks in it, from which fish netting is hung, and fastened at the bottom to stakes driven into the ground 3 feet from the wall to prevent it from being blown against the trees and injuring them. Plum trees were very much blighted last year, and are not so full of

which cropped heavily last year are less promising. Still, we may well look for a good Apple crop. Other hardy fruits also are well set with buds. Oh, for a cool dry March that shall keep all these buds in check, and once into April we may feel that our fruit crops will be safe.—A.

### TRAPPING WOODLICE.

I SHOULD like to bring a simple method of catching woodlice to the notice of Orchid and Fern raisers, also to raisers of Tomato plants and growers of Mushrooms. Last year when we planted Tomatoes we were troubled with wireworm, so placed small pieces of Mangold Wurtzel as traps. When looking for our enemy we found them covered with woodlice. This year we raised 20,000 Tomato plants, and found the woodlice eating off the young plants, so we procured twenty Mangold Wurtzels, cut them in halves, scooped out the middle, and laid them down under the stage. We caught 500 woodlice at a time in one hollowed root—a pailful of pests in one house in a week.—W. WOOD, *Sidcup*.

[Our correspondent has done well in directing attention to this means of enticing woodlice. It is not new, though little known. We have found it excellent for clearing Strawberry plantations of snake millipedes, also the large millipede (*Julus terrestris*), and it is a good trap for the small slugs that are too often found inside ripe Strawberries. The traps should be placed near the plants in good time not later than the flowering period, examining them daily, and changing their positions occasionally. Beetles also seem to relish Mangold Wurtzel, at least they lurk in the hollows of the traps.]

## HARDY FRUIT GARDEN.

**Planting Fruit Trees.**—When spring planting of fruit trees is necessary the first opportunity of doing the work should be taken. Deep digging of the ground is advisable where trees and bushes are to be planted somewhat thickly for furnishing the space at once, thinning out being intended when required. On ground thus prepared the trees for permanently occupying the site may be planted at the usual distances, the ground between to be temporarily filled with bush fruit. Isolated specimens will require stations preparing 6 feet in diameter, or a little less, according to the size of the trees. Deep digging or trenching is only advisable on well-drained ground, whether rendered so by natural or artificial draining. On wet cold soils with damp adhesive subsoils it is better to leave the bottom undisturbed, and to provide a better and warmer root-run above rather than below the surface. The conditions thus secured in unfavourable situations will conduce to satisfactory growth, which may be expected to become properly ripened.

**Obtaining the Trees.**—The best forms of trees for planting in spring when they have to be obtained from a distance are maidens, two-year-old trained and partly formed bushes of this age being suitable. Larger and older trees, well prepared by preliminary liftings to keep the roots at home, move readily from one part of a garden to another, as a quantity of soil can be taken with them, and the removal and planting expeditiously carried out. It is important to preserve as many young fibrous roots intact as possible. Nurserymen as a rule carefully pack the roots of fruit trees in moist material as soon as possible after lifting, thus insuring the trees being delivered to their customers in a proper manner for planting. This must be followed up by the prompt action of the planter in transferring the trees to the quarters intended for them. Should that not be practicable at the time carefully lay the trees in, or keep them in a cool place with the packing material around them. Every care taken of the roots is amply repaid. Trees arriving in a dry state at the roots must undergo resuscitation by plunging them both root and branch into a pond for some hours.

**Hints on Planting.**—The greatest care is required in planting trees and bushes when no soil is attached to the roots. The first requisite is to have the holes wide enough and of such a depth that the uppermost roots will not be covered more than 3 or 4 inches. Wide holes admit of the roots with all their attendant fibres being regularly laid out in a horizontal position. Work among the latter some fine loamy soil, spreading it from the stem outwards, so that each rootlet is encouraged to lay in its proper position. Soil placed heedlessly on the fibres is apt to reverse their points, causing them to grow inwards. Cut all bruised roots smoothly, and remove injured portions. New fibres will issue from smoothly cut roots much sooner than they possibly can from mutilated or jagged extremities. Trees also establish themselves quicker, and better growth follows.

**Treatment after Planting.**—All trees not able to resist swaying by the wind must be securely staked and tied in such a manner that they can subside with the soil. Mulch the surface over the roots with strawy manure or partially decomposed leaves. Heavy decayed manure is not desirable, as it is too close and heavy. The object of the mulching is not to afford sustenance, but rather to conserve the moisture in the surface soil, while affording opportunity for the natural heat to pass through and warm it.

**Pruning.**—This is a matter claiming some judgment. Autumn planted trees will require leading branches to be shortened in proportion to the treatment the roots received. Shortening them to half length usually suffices, lateral growths being cut in to a few buds. Maiden trees, if intended to be grown into trained specimens, must be shortened to a length of 12 to 15 inches from the junction of stock with scion. The number of branches it is intended to take the first year, will, however, afford some guidance. Trees already formed into shape will need but little shortening, especially if the fibrous roots were preserved at planting, and those equally distributed; but if large reductions were made the branches must be shortened to correspond, or unsatisfactory growth will follow. Lifting and transplanting trees with good balls of roots from one part of the garden to another will necessitate no pruning as regards shortening. Weak and crowded wood may be cut out, and rambling roots of a fleshy character curtailed.

**Protection for Wall Trees.**—Moveable protective material should be fixed in good time. Roller blinds or sliding arrangements of tiffany, scrim or canvas, often prove as useful for retarding trees coming into blossom as they do for preserving it and the young fruit from injury. Protection is also needed at times on account of the havoc made by birds, which destroy the buds of Cherries, Plums, Pears, and other fruit trees. Fish nets, however, are best for this purpose.

## FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest House.*—Now the fruit is stoning the temperature must be kept as equable as possible. Too high a temperature, especially at night, is not favourable to the process, and sudden fluctuations often causes the fruit to drop wholesale. The

temperature should be continued at 60° to 65° at night in mild weather, 55° to 60° when severe; 60° to 65° on cold dull days, 65° to 70° when mild but sunless, 70° to 75° with a gleam of sun, ventilating early and freely under favourable climatic conditions. Thinning the fruit must be seen to, not allowing twice as many fruits to stone as are to be left for the crop, but a few more than the required number should be retained to meet casualties in stoning. One fruit to a square foot of trellis covered by the trees is a fair apportionment; small-fruited varieties may have the fruit left a little closer, and vigorous trees will carry more than weakly trees. Overcropping, however, must be strictly avoided. Nectarines require the same space as Peaches to have fine fruit. Secure all the shoots to the trellis as they advance in growth, stopping any that are likely to exceed 12 to 15 inches at those lengths, and if the pinching results in laterals stop them at the first leaf. Shoots retained to attract the sap to the fruit should be stopped to one leaf. Extensions should be trained in their full length, pinching laterals at one joint as made. Syringe the trees in the morning and afternoon when the days are fine, but damping available surfaces will be sufficient in dull weather, with an occasional forcible syringing, to keep red spider under. If the pest gains a footing extirpate it by the prompt application of an approved insecticide, or a solution of softsoap, 2 ozs. to a gallon of water. Inside borders must be duly supplied with water or liquid manure in a tepid state, but avoid over-stimulation whilst the fruit is stoning.

**Second Early House.**—Disbudding must be proceeded with gradually, and the successional bearing shoots should be laid in as soon as they are sufficiently advanced in growth. Thinning the fruit must be attended to as soon as the remains of the flowers are cast. Remove all twin fruit, the smallest, that on the under side of the branches, and the badly placed, leaving three on a branch of 12 inches length, to be afterwards reduced to two on a strong and one on a weak branch when of the size of marbles. Only one fruit as a rule should be left on each bearing shoot, but two may remain if there be a deficiency in other parts of the tree. The fruit will rapidly swell to the size of small Walnuts, the temperature by that time having been increased to 55° to 60° at night, 60° to 65° by day from artificial heat, and 70° to 75° from sun heat, with a free circulation of air from 65°, avoiding cold and drying currents. Syringing the trees twice a day in bright weather, and occasionally in dull weather, with damping the floors once or twice a day will keep red spider under, and maintain a genial atmosphere.

**Succession Houses.**—Trees now in bloom require a free circulation of air, or such as will keep the atmosphere buoyant with sufficient fire heat to prevent sudden depression of temperature, maintaining 50° at night or a few degrees less on cold nights. A temperature of 50° to 55° will be suitable in the daytime, advancing to 60° or 65° from sun heat with free ventilation. Shake the trellis or trees occasionally to distribute the pollen, or preferably, pass a camel's-hair brush or feather over the flowers that have ripe pollen once a day, and give extra attention to the shy-setting varieties by conveying pollen from others that produce it in abundance, as for instance Royal George and Stirling Castle Peaches, also Elruge Nectarine. Keep the paths well damped on fine days, and be more sparing of water when the weather is dull and cold.

**Late Houses.**—The roof lights need not be put on until the buds show the silvery integuments that envelope the floral organs, but they are not safe after the blossoms show colour. Trees under fixed roofs are more forward, the buds being in various degrees of expansion. Where syringing has been practised it must be discontinued as soon as the anthers show clear of the corolla, but damp the floor in the morning and afternoon, leaving a little air on constantly at the top of the house. No more fire heat should be used than is absolutely necessary, but after the flowers show the stamens a certain amount of warmth is needed, for when the atmosphere is cold and moist, and the flowering extends over a considerable period, the fruits do not set well; therefore, after the blossoms open maintain a temperature of 40° to 45° at night, 50° to 55° by day artificially, with a free circulation of air, advancing to 65° with sun. In the case of weak trees having a superabundance of blossom it is advisable to remove the flowers from the under side of the shoots or the back, as the trees may be against front or back trellises. The borders should be kept healthfully moist.

**Figs.**—*Earliest Forced Trees in Pots.*—The fruits will soon have completed their first swelling, and they then remain apparently stationary for some time. This is the most critical stage in their culture, and every care must be taken not to give a check, whether caused by excessive heat or want of moisture. In mild weather the temperature may be kept at 60° to 65° at night, but if cold 5° less will be found safer. Progress is best made in the daytime by closing with plenty of heat and moisture, a rise being indulged in of 10° to 15° without producing a weak or elongated growth, keeping through the day with gleams of sun at 70° to 75°. Red spider must be kept under by copious syringing on all favourable occasions. Afford a steady supply of liquid manure to the roots, as Figs in full growth require generous support, and can hardly be over-watered, provided the drainage is thorough.

**Succession Houses.**—Crowded growths must be thinned, but they are better prevented by disbudding, leaving no more shoots than space permits. Where extension or successional growth cannot be allowed the shoots may be pinched at the fourth or fifth leaf to form spurs, these giving good results in the second crop; but avoid crowding as the greatest of evils. Syringe the trees twice a day, and keep the borders well supplied with tepid diluted liquid manure.

**Young Trees in Pots.**—Those intended for next year's forcing should

be shifted into larger pots, and be placed in or over bottom heat. The compost may consist of good yellow loam, with a sixth of old mortar rubbish and a sprinkling of crushed bones, say a 6-inch potful to a bushel of loam. Provide good drainage, pot firmly, and do not let the shift exceed 3 inches in diameter that of the previous pot. Shade slightly from bright sunshine for a few days until the roots have taken to the new soil, when the trees should be fully exposed to light and sun. Pinch the growths at about four leaves to induce a bushy habit.

**Cherry House.**—The main art in forcing Cherries is attention to the ventilation; a free circulation of air should pass through the house whenever the temperature exceeds 50°, the amount of air being regulated by the condition of the outside atmosphere. Fire heat need only be employed to prevent the temperature falling below 50° in the day-time, and to maintain a night temperature of 40° to 45°. Attend to fertilising the blossoms with a camel's-hair brush or a feather. Aphides generally appear just as the trees set their fruit. They must be destroyed, or they will ruin the growths and spoil the Cherries. Grubs also infest the foliage; one kind of caterpillar rolls itself up in the leaves, and can be extirpated by squeezing; but another encases itself in a web on the under side of the leaves, and they appear as if scalded, and from the foliage the pest makes its way to the fruits and devours them. The surest means of riddance is to examine the trees occasionally and destroy the grubs.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

WE have had slight showers of hail and snow, inclining to frost, the lowest temperature for the month being 25° on the morning of the 24th, and the highest 55° on the 19th, thunder being heard in some places. On that day, the 19th, the bees gathered pollen from the various flowers in bloom, and in quantity where the Hazel catkins were profuse. Upon the whole the bees have been kept more within the hives than during any February for many years past. This, according to weather prophets and old saws, augurs well for a fine summer, and I hope we shall have one.

#### APPLIANCES.

These should be overhauled and put in good order, so that when required there will neither be necessity to search for them nor to put them into condition when there is not time to spare to do so.

#### INTERCEPTING SWARMS.

When I described my swarm interceptors I omitted to say that light, handy, and easily made ones may be constructed of wire cloth; if necessary line with calico on the principle of the swarm catcher and hiver, or they may be made with wire crown cloth lined with calico. They are handy swarm catchers and hivers in all situations.

#### YOUNG BEES.

In hives with youthful queens young bees are now numerous, and are the best for early work. The wide-awake bee-keeper will not tolerate queens older than those of the preceding year; but occasionally circumstances may have prevented the alternative, yet these need not be kept in the apiary longer than May. By that time young queens can be easily bred and fertilised in time to supersede aged ones, and with extra breeding space are the best and only means to prevent swarming in storified hives. Hives properly managed on the swarming system, where the honey season does not commence before the middle or last week of June, are by far the most profitable; besides, there is no risk of a hive collapsing as a non-swarming one with a worn out queen frequently does. Only last year "W. B. C." said in the "Record" that swarms of the current year were profitless, or words to that effect. That teaching may please novices, but practical bee-keepers smile at the absurdity. Our first swarms are those on which we depend for large yields of honey of the finest quality, provided the bees issue several weeks before or at the beginning of the honey flow. In the event of the queen of a swarm relaxing in egg laying at a time that would affect late honey gathering I depose her, and introduce a young but fertile one as early as possible. My safety cage shows at a glance whether it may be safe to release her or not. Many claims have been laid to "direct introduction," but the fact remains that the term is misleading. There is no safe method of direct introduction. The queen regnant must first be deposed, and the bees have time to realise their loss before it is safe to allow an alien queen in their midst.

#### VARIETIES OF BEES.

It would be very interesting as well as instructive were bee-keepers to note the various characteristics of their bees, their

faults or failings, as may be observed throughout the year. I have no hesitation in affirming that the Carniolan is the hardiest of any race of bees; also mild in temper, as well as good and cleanly in storing honey. Strongly do I wish also that some of those renowned bee-keepers who have said so much against Punics were here in a good honey flow to witness the energy of these maligned bees. I hope we may have several honey days in succession the coming summer to test the pure ones. Syrians, like the crossed Cyprians, have also proved good honey gatherers. I have not fed mine for years. The large gathering of 33 lbs. in one day was by crossed Syrians.

#### FASTENING COMB FOUNDATION.

One thing I have omitted to say. Where foundation is fixed with wax in a groove or between a split bar the work may be performed at any time; but where it is done by pressure it is better to postpone the fixing till near the time it is wanted. If done earlier the movement of the wood by contraction, and the absorbing of damp, causes the foundation to part from the bar or section. This causes extra labour, and if unobserved crooked combs.—A LANARKSHIRE BEE-KEEPER.

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Clivias (G. F.).**—You do not say with what object you have sent the truss and foliage. We can only say that they represent good cultivation. You have evidently a good form of *C. miniatum*, but some of the newer varieties have much larger and better shaped flowers.

**Double Primulas (John Laing & Sons).**—You ask if we do not think the seedling Primulas good. Though the cotton wool extracted moisture from them, and thereby caused a shrinking of the blooms, we could still perceive they were very good, not semi-double, but full rosettes in pleasing colours, white, blush, pink, and rich carmine.

**Removing Mushroom Beds (Humber).**—It is certainly unfortunate, after waiting so long for Mushrooms, that you should have to leave the beds for someone else to enjoy the crops now appearing. As the beds on the shelves can be removed bodily, and they appear to be worth the trouble of transport, we see no reason why you should not carry out your novel proposition. We suspect it would be the first instance on record of transplanting Mushroom beds. Breaking up the beds and removing the materials for use again would be more likely to result in complete failure than even partial success.

**Manure for Mushrooms (E. M.).**—The ammonia which you wish to preserve is retained in the judicious preparation of suitable manure, as is evident by the bountiful crops of Mushrooms that so many persons obtain. Throwing manure in too large heaps and allowing it to heat violently, then turning it over and over again to cool, is the best method of dissipating ammonia and spoiling the material for Mushroom growing. The manure should not heat violently but ferment gently, and ought only be turned till the effluvia ceases to be offensive; it should be pungent yet not unpleasant, then if moist enough for steady fermentation to continue its condition will be right for the purpose in question; but excessive moisture is pernicious.

**Constituents of Plants (J. H. E.).**—If you could obtain what you ask for, "the constituents of each of the various fruits and vegetables grown in this country," you would be more bewildered than benefited in respect to providing manure for them on that basis. As a matter of fact, analyses vary in accordance with the constituents of soils, and before you could with exactitude compound a manurial mixture the most appropriate for each fruit and vegetable you would also have to obtain a quantitative analysis of the particular soil in which each is intended to be grown. Some soils naturally contain more of some particular plant requisite than others do, and the variation is often very great over a small area. Manuring on the basis of an analysis of plants or crops alone may result in waste. For instance, potash might be shown as the leading constituent of a plant or crop, and at the same time the soil may contain infinitely more potash than the plant or crop can possibly use. Obviously, then, to spend money on more would

be to waste it, and an outlay in phosphates might be far more profitable. Experiments conducted over and over again have shown that suitable additions of nitrogen, potash, and phosphates are sufficient for producing maximum crops of all kinds under otherwise good practice in cultivation; and in the absence of essential cultural details, apart from manuring, storing the soil with exactly what crops need, may have no profitable result. If you can enable us to comprehend the nature and condition of your soil, and the crops you desire to grow, we think we can give information that will enable you to use chemicals reasonably, as well as farmyard manure.

**Measuring Trees (A Young Gardener).**—You are right; the art of measuring trees is not so well known amongst young gardeners as it ought to be, and we have pleasure in advising you and other inexperienced readers as to how it may be done. Mr. Harding, the gardener at Orton Hall, near Peterborough contrived the simple home-made appliance shown in the accompanying illustration (fig. 40), and by adopting this means one can ascertain the exact height of Conifers and other trees. The tree measurer on the right of the figure consists of a staff 6 feet long pointed for pressing into the ground. To the centre of the staff a piece of half-inch board 12 inches wide and exactly square is affixed with screws. The diagonal cross lath is 3 feet long and perfectly straight. It may be fixed or moveable; if the latter, a small

FIG. 40.

batten being screwed on the board for it to rest on when in use. The plumb line is indispensable, as no correct measurement could be had without it. The plumb-bob may be about the size of a small Walnut, the string passing through its centre, then knotted to make all secure. In measuring the tree the staff is placed at a distance from it so that with the plumb exactly perpendicular, the cross lath points to the top of the tree, the person taking the "sight" resting on one knee or reclining to bring the eye to the bottom of the lath. The lath is then drawn to the ground, where the end rests at C in the figure, or if the lath is fixed a string will answer the purpose of extending the sight line to the ground. From this point C to the centre of the trunk, not the face of it nearest the point, but the middle, will represent the actual height of the tree; or to put the matter concisely, the horizontal line, A C is equal to the vertical A B; and if the tree were blown or cut down its top would follow the course shown by the curved line and rest at C. If a tree has several leaders, as *Pinus excelsa* and some others often have, the sight should be taken of the most central one, or nearest in perpendicular with the roof of the tree, not a side branch that may happen to be a little taller, as the base line would then not give the true height of the specimen. On level ground it is easy to perceive that altitudes of a number of trees can be quickly ascertained. When the ground is irregular provision must be made for having the line level from the root of the tree, or A in the figure to C. The central board, it may be repeated, must be a true square, the perfectly straight sighting lath resting across it exactly from corner to corner, as the least deviation will lead to error, and the weight must hang positively plumb, as not otherwise can the measurement be accurate. Any handy man can make an appliance of this kind.

**Cordon Pears (J. B.).**—You have overlooked exactly what you wish to know. The pruning is not only described but illustrated in Wright's "Fruit Essay" (see pages 95 and 96). The trees will answer very well trained to stakes along the sides of garden walks. We know of hundreds so grown forming lines of fruitful cordons 9 feet high—the trees planted about 2 feet asunder or a little less. Do not shorten the leader except it terminates in a fruit bud, in which case cut back to a wood bud. The side growths may be shortened now, as the few there are can exert no material influence in the promotion of roots. You would find Wright's "Primer of Horticulture" useful, this principle of pruning being shown in connection with cordon Gooseberries on page 105. Your letter arrived too late for insertion this week, as our pages had to be made up earlier than usual, to afford the printers time for producing the extra large number of copies required at the hour of publication.

**Arrears of Wages (J. W., Gardener).**—We could better understand the case if you had sent copies of the letters on which the engagement was based. If we comprehend what you wish to know chiefly it is this: "Whether you can retain possession after the expiration of a notice to leave that may be served on you by an employer on the grounds that the said employer is in arrears in paying your wages?" If that is your question we suspect that the fact of money being owing to you by your employer and landlord, does not debar him from ejecting you at the expiration of the term of a proper notice to leave. Your remedy is to sue for the arrears, and this you can do at any time, either before or after leaving your situation. The case as you state it is, we hope, a very rare one.

**Duties of Gardeners (J. S. B.).**—As you are evidently a young man without experience in, as you say, a "large" garden, the very best way in which you can obtain the information you seek is by obtaining employment, not so much in a very large, as in a moderate sized garden where most of the duties of a gardener are carried out well. You cannot possibly learn from books what a good gardener can teach you. Strive for a situation under one, then be obedient, punctual, observant, diligent, obliging, and industrious. These are the first cardinal duties of a young man, and after he has had a little experience he will be the better able to comprehend the teachings of books. In the meantime read attentively the *Journal of Horticulture*, and file the copies for future reference. You will then soon have a valuable store of information on almost every subject in connection with gardening.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (G. F.).—*Cattleya Trianae rosea*, very poor form indeed.

### SPRING CROPPING—POTATOES.

UNDER good management this is so profitable a crop that it should be cultivated much more extensively near every large town than it is, or we might add, on farms within reasonable distance of a town or railway station in view of a prompt and profitable disposal of it. If it answers to grow Potatoes for the London market in Scotland, it certainly ought to do so in southern or midland farms. Many a farm do we know with every advantage of soil and situation where Potato culture never enters into the general scheme of cropping, and yet a field or two of Potatoes would certainly prove a profitable investment. It is probably owing to the risk of loss from disease that the ordinary farmer so seldom attempts growing more Potatoes than are required for his household, and so it has come to pass that certain districts have a monopoly in the supply of home-grown Potatoes. Custom rules in this as in most other things affecting farm management, and in the great corn-growing districts there are very few farmers who have turned to such things as Potatoes, fruit, or butter to help them in their need. How they cling to corn is shown by the fact of some 17,000 acres more land having been under Wheat in 1892 than in 1891 in the counties of Lincoln, Norfolk, and Suffolk.

Notwithstanding the reports of much land out of cultivation in Essex, many of the farmers in that county do better devoting part or the whole of their land to dairy farming, or to the cultivation of fruit and vegetables. It was here that we saw heavy crops of Beauty of Hebron Potato lifted for market while the haulm was quite green last summer, and the planting of successional crops of green vegetables for winter and spring use. There was no loss from disease simply because the crop was cleared and sold before disease could touch it. No better sort of Potato than Hebrons could be had for such smart practice. Well was it described in the report of the Woburn experiments on Potato disease last year as a "good early cropper, clean skin, shallow eye, very saleable." Be it remembered this applies to it as a field Potato, which answered admirably under ordinary conditions of culture, when Myatt's Ashleaf growing beside it was comparatively a failure.

Beauty of Hebron, Reading Giant, and Emperor are among the best early, intermediate, and late sorts, in the order they are named, for field culture. They are all heavy croppers, and full crops are quite certain to be profitable if heavy losses from disease can be avoided. That this can be done by the timely and persistent use of bouillie bordelaise appears probable, and the outlook for Potato growers seems brighter than it has done for many years. The chief points requiring attention are soil well tilled and well manured; seed of medium size, carefully selected, and so managed that it sustains no loss of vigour from premature growth before planting; the prevention of loss from disease, and the judicious sale of the crop. Deep, rich, alluvial soil, like that in the fens, may be best; but we have had very heavy crops in soil that is naturally poor and thin on the Hastings sand formation, and are bound to regard all sound loam and mixed soils as well adapted for the successful cultivation of this crop. There must be no placing of the seed Potatoes in heaps during the winter, or there will be much abortive growth. Many a heap have we seen opened at planting time with long, slender, white growth from the tubers interlacing the whole mass, representing just so much wasted vigour. It must surely be worth while to avoid this by spreading out the seed tubers thinly—preferably in single layers in some building having windows for the daily admission of light, and yet out of which frost can be kept.

The best plan of all is that of placing the tubers on end, with the eye end upwards, on shelves arranged in any convenient way; and though we have been asked how any farmer can be expected to have time or convenience for doing this, it is obvious that a man resolved to do his best is bound to adopt the best method of seed preparation. If in the autumn tillage of the land that portion of it intended for Potatoes was thrown into ridge and furrow, making the furrows the right distance apart for Potatoes, when planting time comes the work is done expeditiously and in the best way. There are the furrows ready to our hands; we have only to apply manure, place the seed in the furrows, level down the ridges, and the work is done. An excellent chemical manure for the purpose is made by mixing one part kainit, or half-part of muriate of potash, with three parts of superphosphate, adding one part nitrate of soda for poor land, and using from 4 to 5 cwt. per acre. This is sown broadcast over ridge and furrow at the time of planting.

### WORK ON THE HOME FARM.

Reports from districts situated widely apart tell of arrears of ploughing. This is a serious matter, especially on stiff land farms, for the soil has been so saturated by an exceptionally heavy rainfall in February that it can hardly be got into condition for sowing till late in the season. Every spring shows how invaluable autumn tillage is, yet the difficulties involved in ploughing arrears would seem to have no influence upon autumn work. Let spring corn show a full plant before sowing Clover or mixed seed among it, but lose no time in sowing the fodder crops as soon as the Barley or Oat plant is visible along the rows. Push on all sowing when the soil is dry enough for the work to be done expeditiously and well. Finish under-draining now on pasture, get the sods placed carefully on the soil in the drain trenches as soon as possible, pass a heavy roller over each line of sods to press them well into the soil while it is moist, and follow at once with chemical manures wherever they are to be used. Clear up all broken drain pipes and see that everything is neat and in perfect order before each portion or job of work is left. Pasture generally is very bare, no cattle can be out upon it for some time, and the beneficent effect of regular manure dressings will tell well now, as it is only by such sound practice that an early bite on pasture is possible. Where Rye is at all backward it should have an immediate dressing of nitrate of soda at the rate of a hundred-weight per acre, and it will then soon be ready for folding ewes and lambs upon. After the folding it may be left to grow again and be harvested for the seed and straw, or it may be ploughed at once for drilling Thousand-headed Kale.

Follow Swede folds closely with the ploughs, and sow either spring corn or fodder crops without delay. Do not forget how useful two or three successional sowings of Vetches are. Some land to be laid down to permanent pasture has been sown with Oats, which will be most useful next winter; the Grass and Clover seeds will also soon be sown, and we may expect enough herbage upon it next autumn after harvest to make it worth while passing the sheep over it, but they will be withdrawn by the end of September.

### METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

### REMARKS.

19th. —Lightning soon after midnight and about 3 A.M.; rain till 3.30 A.M.; sunny and warm all day.  
 20th. —A little sun early; overcast, with occasional drizzle till mid-day; bright sunshine from 3 P.M.; cloudy evening and rain after 10.30 P.M.  
 21st. —Rain early and from 9.30 A.M. to 1.30 P.M.; fair afternoon, but rainy again in evening and night.  
 22nd. —Almost continuous rain or wet snow from 0 A.M. to 7.30 P.M. but very slight after 1 P.M.  
 23rd. —Enough snow to cover the ground about 4 A.M., nearly all melted by 9 A.M.; overcast throughout.  
 24th. —Overcast, with occasional small flakes or single crystals of snow falling in morning; gleams of sun after 3.30 P.M.  
 25th. —Bright sunshine almost throughout.  
 Temperature near the average, barometer much below it, in fact unusually low. Rainfall more than double the average.—G. J. SYMONS.

## THE RAILWAYS AND THE PUBLIC.

POWERFUL as is the great railway organisation, there is not wanting evidence that the British public is still more powerful. The proposed rates for merchandise as determined by the concerted action of the companies cannot be sustained, and there is a general tendency to return to the old scale, coupled with the repayment by the companies of what may be called the excess charges that have been enforced. If it had been possible for the higher rates to be maintained the effect would have been disastrous, and shareholders must have eventually suffered; but the great community of producers would have suffered the first and the most, while the prices of goods to consumers must have been materially enhanced. The ultimate effect of the new changes would have amounted to a tax on food, and as no Government is strong enough to impose any such tax, even if disposed, it was not to be expected that the public would allow any trade organisation, however powerful, to do so; and hence the whole country, so to say, rose in rebellion at what was felt to be an unbearable imposition.

The new rates would have had a ruinous effect on farmers, and especially on market gardeners, and the case made out by the recent deputation of the latter to the Board of Trade was unmistakable. The facts stated by Messrs. Berry, Poupert, Monro, and others were of the most crushing character, and such as no Government could ignore. When it is made clear that the difference between the old rates and the new for certain garden produce would amount to an increased rental of £5 an acre, the impossibility of the proposed charges is too obvious for argument, and a modification of recent rates becomes imperative.

The subsequent Parliamentary action, in which Sir A. Rollit and Sir James Whitehead figured prominently, and the result of their presentation of the case, leave no room for doubt that the new rates, broadly speaking, must go. It is due to Sir James Whitehead that his services be acknowledged. In and out of Parliament he has laboured incessantly in the public interest on the question of railway charges, and his undoubted ability and great tenacity have contributed largely to the results which have been so far achieved, but more remains to be done till the matter is placed on a perfectly satisfactory basis.

It is quite enough, in fact a great deal too much, that the preferential charges by which French and Dutch producers can place their goods in our markets at lower rates than Kentish and Essex growers are allowed; this, we say, is quite enough without further impositions being made that amount to a tax on home industries and the correlative crippling of trade. The railway companies have made a mistake. The practically formed syndicate is breaking up, shareholders will have to pay for the error in judgment in the form of reduced dividends, and the only hope for an increase of these rates is the expansion of trade, and clearly this cannot be developed by prohibitive rates for merchandise. As the riches of the railways have been mainly provided by the lowest scale of passenger fares, paid by the million of travellers, it may be hoped a reduction of terms for small consignments will be effected with the object of increasing the number of such consignments to the material advantage of producers and carriers. It is in that way prosperity lies, the opposite leading to stagnation and national discontent.

## LAND AND ESTATE DECADENCE.

### AN IMPEACHMENT.

I HAVE received the following letter from one of the best of British cultivators and estate managers. It is so trenchant and suggestive that the public who are interested in land cultivation ought to have the opportunity of reading it. The writer of the letter gives utterance to home truths in no hesitating manner, and as he is not a young enthusiast, but has had half a century's experience in land improvement, in which he has successfully shared, he is entitled to be listened to on that account.

He is earnest in the desire to see the gardeners of the future in the fullest degree competent, and several of his pupils worthily occupy responsible positions. He rebukes the frivolity of those heirs to estates who pay little or no attention to their improvement, but, on the contrary, impoverish them by indulging in the luxuries of life. He condemns the absurd practice of appointing agents who are necessarily ignorant on subjects which are the root and basis of successful management. He deplores the decadence of old families, and is deeply concerned that so many gardens are being ruined that dogs may be pampered and sport flourish. More in anger than in pity does he look facts in the face—facts, too, that he feels are of vital importance as affecting the best destinies of the nation. The letter was not written for publication. It is, perhaps, all the better on that account, and the great majority of the readers of the *Journal of Horticulture* will, I think, agree that it is worthy of a better fate than the waste paper basket; and at least they shall have a chance of judging. Here it is:—

"Your 'Primer' is bound to be useful to the million if they will read and digest. Would that young gardeners, as a class, would study the natural sciences that bear directly on horticulture. Both in agriculture and horticulture the state of matters in this respect, from the proprietor and his estate agent downward, is deplorable. I am certain if ten of our estate agents were asked what effect caustic lime has on land, the answer of nine would be a blank stare!

"In the first place, the heirs to estates are taught everything and anything but estate management, and in the majority of cases the management falls into the hands of a lawyer or half-pay captain. Is it any wonder the land interest is depressed? The marvel would be in these times if it were not. Fancy any of our large ship-building yards or any mercantile affair managed with as little knowledge scientifically of their business as agriculture is managed. What would be the result?

"The landowners are in many cases in difficulties. If they had made their land a study and lived reasonably they might have had splendid bank accounts, whereas they have not a peg to stand on. Gather up the rents, and go and squander them on all sorts of things but estate improvement! It takes £4,000,000 a year to keep up the hunting establishments of Britain, and what good does it do? The last thing to be reduced are the kennels and keepers, and useless horseflesh.

"I am grieved to see our fine old aristocratic gardens and estates in such a plight as they are in so many instances falling into. Want of order and high culture prevail where once the reverse ruled. Doubtless the masses are being reached by horticulture and its products as they never were before, and that is a blessing; but for what have we to thank the so-called managers of many estates?"

Though I know there are many gratifying exceptions to the conditions indicated in the above letter, the facts set forth cannot easily be refuted. There are prudent proprietors of estates who devote their attention to improvement, and there are competent and diligent managers, but all the same it is deplorable to note the spendthrifts in high places, who bring ruin to estates and misery to districts; and it is unfortunately true that persons are entrusted with the management of property whose training has been on wholly different lines, and whose tastes lean in the direction of sport rather than productiveness. Not a few of the most successful stewards and directors of estates were once gardeners—men of education, intelligence, business aptitude, and cultural skill. These men have been trained to habits of economy, and also to

regard expenditure as a profitable investment as far as circumstances permit. Against waste even in small things they resolutely set their faces, and their practical knowledge enables them to determine the cost and value of undertakings, and the return that should rightly accrue from expenditure. Half-pay captains and impecunious college chums cannot be compared with such men as wealth producers, for they know not the way; while the latitude given to many lawyers in the conduct of estates from a cultural and productive point of view is an anomaly.

I regret as much as my correspondent can do the decadence of estates and unproductive expenditure for personal gratification when matters of far greater importance are neglected. My friend is a Spartan in character, and as a stern utilitarian no doubt believes the old ways in working for profit are better than the new methods that have become established. I will ask him which he prefers of the following representative types:—

## OLD.

Man to the plough,  
Wife to the cow,  
Girl to the sow,  
Boy to the mow,  
And your rents will be netted.

## NEW.

Man tally-ho,  
Miss piano,  
Wife silk and satin,  
Boy Greek and Latin,  
And you'll be gazetted.

—J. W.

## FLOWERS AND PLANTS FOR AUTUMN.

MICHAELMAS Daisies are suitable for decorative purposes in the cut state. The species I grow most extensively is *Aster Amellus*, which is distinct and continues in flower until cut down by frost. *A. versicolor* is also valuable, and the two late flowering species *A. novæ-angliæ* and *A. novi-belgi* are particularly good. *Eryngium maritimum* is another useful plant for cut purposes, and the same may be said of *Helenium pumilum*. *Chrysocoma Lynosyris* is not so valuable as *Helenium pumilum*, but it is well worth growing, and so is *Rudbeckia Newmanni*. Some of the *Delphiniums* are very useful during the autumn, but whether they are in flower or not at this time depends greatly on the summer treatment. Either do not let the plants bloom in summer, or if they do this cut down the stalks immediately after flowering. *D. formosum* is perhaps the most useful of any. *Solidago canadensis* is serviceable, and so is *Chrysanthemum maximum*. The best *Chrysanthemums* we yet have are such as *Précocité* and the *Madame Desgranges* family. Of these a large number ought to be grown. I also like to have a few *Fancy Pansies* and *Tropæolums*, *T. canariense* being quite indispensable. Spotted *Mimulus* are also pretty and last well, and the value of *Roses* is well known.

Among the flowers cultivated under glass *Celosia pyramidalis* is of much value, and *Ivy-leaved Pelargoniums* are useful, *Souvenir de Chas. Turner*, *Galilée*, *Madame Thibaut*, *Le Printemps*, and *Madame Crousse* being especially good. Single yellow *Tuberous Begonias* will prove serviceable, and *Countess of Aberdeen Fuchsia* is an excellent variety when used in a cut state. *Liliums*, too, should be grown extensively, especially *Lilium speciosum* and *L. auratum*. *Allamanda Hendersoni*, *Eucharis amazonica*, and *Bougainvillea glabra* should likewise be grown for providing cut flowers.

Of foliage, the most suitable for decorating is *Maidenhair Fern*. If the plants have been kept in an airy vinery throughout the summer the fronds will last in a good condition for a long period. *Asparagus tenuissimus* and *A. plumosus* are also valuable. *Smilax* is useful, and plants may be obtained from seed sown in spring and grown quickly. Like the *Asparagus* and *Fern*, this is of the very easiest culture. Coloured *Crotons* and *Dracænas* are both of great value. Commoner material will be found in the foliage of *Gladioli*, *German Irises*, *Solomon's Seal* (especially when the berries begin to colour), and *Thalictrum minus*. I also employ *Dahlia* shoots with buds, *Azara microphylla*, *Brambles*, *Sedges*, *Rushes*, *Reeds*, and *Bamboos*, and occasionally the foliage of *Pampas Grass*.

In cases where many plants are needed for apartments this is the time to commence getting together a sufficient stock. There are a few good flowering plants that are quite easy to grow, and which can be dispensed with if the ordeal of a week in a hot room proves too much for them. But, as a rule, by observing the adaptability of various plants one can save them for future use by changing at short intervals. In this way I make a practice of having a large number of *Zonal Pelargoniums* of purple or lilac shades, tinted rose being unsuitable. The best varieties I have

are *Brilliant*, *Freya*, *Chas. Mason*, *Rev. H. Harris*, reds; *Stella Massey*, like *Apple blossoms*; *Lily*, nearly a white; *Amy Amphet*, white; *Constance*, pink; *Helen Clarke*, and *Sissie*, salmon. A few good doubles are *M. Bruant*, *Meteor*, *L. Constable*, *Hermine*, *F. V. Raspail*, and *Gloire de France*. Double *Ivy-leaved Pelargoniums* are useful, the best for the purpose being *Madame Thibaut*, *Le Printemps*, *Alice Crousse*, *Madame Crousse*, and *Galilée*. Small plants of *Fuchsias* are also good, especially *Countess of Aberdeen*, which is an excellent decorative plant. I also like *Rose of Castille* for this purpose, and of doubles the very best I have tried is *Mrs. E. G. Hill*, the habit of this variety being perfect. *Begonias* are also serviceable for autumn, but though seedlings of the same year are, as a rule, too small, plants two years old are first-rate. These may be grown in a cold frame, and they make sturdy plants with little trouble. I also use a few of the double varieties, such as *Rosamonde*, *Fuljurant*, *Louis d'Or*, and others which are plentiful. *B. Weltoniensis* and *B. Carrieri* are both first-rate, and the ever-blooming and beautiful *B. Gloire de Sceaux* may be also used. *Celosias pyramidalis* and *plumosa* are quite indispensable. They are easy to cultivate, are of great beauty, and bear rough treatment almost with impunity. I grew several good strains last year, but I think of the whole none is so fine as the *Drumlanrig Yellow*, which is of a fine gold shade. A few well-grown plants of *Campanula pyramidalis*, more particularly the white-flowered form, do good service in early autumn. *Lilium auratum* and *Lilium speciosum* it is most necessary to have as pot plants. Good sized bulbs can be grown in 5 and in 6-inch pots, but when grown in such small pots they require to be well fed and generally well treated. *Carnations* are not so much appreciated in the autumn. I have had plants in pots at that season, and they were most serviceable. In March I intend to pot some layers for flowering in the forthcoming autumn. Good plants can be well grown in 6-inch pots, and for the very strongest 7-inch pots are large enough. I also like to have small plants of *Harrison's Musk*, *Campanula isophylla alba*, *Lobelia's Lady McDonald* and *Wave of Blue*.

Foliage plants include *Palms* and specimens from 4 to 6 feet in height, of the variegated and green *Ficus elastica*. *Pandanus Veitchi* is so serviceable that a large number of this is always worth trying to secure. *Dracænas indivisa*, *Veitchi*, *rubra*, *Lindeni*, *ferrea*, *Cooperi*, and *superba*; *Crotons interruptum*, *aureum*, *angustifolium*, *Johannis*, and *Countess* are perhaps the best of these plants. *Grevillea robusta* grown rapidly from seed sown in early spring or from cut-back specimens is a useful plant, and so is the green-leaved *Cyperus alternifolius*, which is most readily raised by means of seed. Seed of *C. distans* sown in spring produce good plants by the autumn. The *Aspidistras* ought to be divided in the spring and grown all the summer in a moist heat and shade. *Asparagus plumosus* is best raised from seed sown in spring, and old plants of *A. tenuissimus* trained to a single tall stake are very effective. They keep in good condition grown in 6-inch pots provided stimulants are given and no neglect in watering occurs. Plants of *Ficus repens* in small pots and with long drooping stems, along with a good supply of *Panicum variegatum*, and of *Smilax* grown from spring-sown seeds, are most useful. I always grow a number of *Caladiums* in small pots, and through the summer the plants do well in a cool house. It is astonishing how well the apparently delicate foliage keep when in rooms. A supply of *Coleuses* helps wonderfully, and the best variety for the purpose is *La Tête d'Or*. The habit of this is dwarf, leaf well developed, and the foliage is beautifully coloured. An abundance of *Maidenhair Ferns* is imperative, and they are easily grown. Along with the above *Isolepis gracilis* may be named as a very useful little plant. It can either be raised from seeds or by division of the plants in spring. In addition to those mentioned there are other valuable plants, but I think the foregoing will be found a good selection to get together to assist a gardener through the busy months of the autumn.—R. N.

WELLINGTONIAS VERSUS AUSTRIAN PINES  
AS WIND TREES.

RECENTLY I noticed in the *Journal of Horticulture* (page 154) Mr. Molyneux drawing attention to the unsuitableness of *Wellingtonias* for exposed positions, or to form screens against high winds and gales, and I can quite bear out what he says. As at Swanmore, we too are subject at different seasons to heavy gales from the south-west, and in each instance where these trees are exposed to them they form a one-sided and unsightly appearance, while others planted about the same time but in more sheltered places grow freely and form handsome specimens. Mr. Molyneux has done well in warning intending planters against using *Wellingtonias* in such exposed positions; but I will go a little farther, and advise

all who are anxious to plant for protection to substitute for them a most valuable tree for the purpose—viz, the Austrian Pine.

Austrian Pines are great favourites here, and many thousands have been planted on the estate from time to time. Not only are they valuable to block unsightly objects and to form a break against high winds, but they are conspicuous in the landscape, and for this purpose few trees are their equal, especially during the winter, when they seem to give a tone of warmth to the whole surroundings, which deciduous trees can never give, let them be planted ever so thickly.

We have recently planted many more "Austrians." In one case 600 were used in one clump some two miles from, but still in view of the mansion, on a most exposed and elevated position. In spite of that, out of this number we only lost three—a convincing proof I think of their suitability for such a position, but we should not have succeeded so well had we not selected the right time to plant them. To have placed these in such an exposed place several months or weeks before growth had commenced would have been courting the death of many, and this I think is the great secret in establishing them—delay planting until growth has commenced. These under notice were not planted until the first week in May, a little too late perhaps, as the young growth, some 2 or 3 inches long, flagged, but after a good soaking, and the rain, which shortly followed, they commenced to grow, and have continued to make good progress.

Whether for shelter or landscape effect they should not be planted too thickly, neither should much underwood or deciduous trees be planted near them, as this would cause the lower branches to dwindle away, and the tree might soon become top-heavy, under which condition it could not be expected to withstand many severe gales. I have experienced this recently, where several trees in mixed plantations were blown over, while isolated specimens withstood the force with seeming impunity.

On the east and exposed side of a large orchard in this neighbourhood a double row of Austrian Pines are planted, and I have more than once proved the great protection they are to the fruit trees, not only while in bloom, but also when loaded with fruit. I do not suppose anyone would recommend the planting of the Austrian Pine with a view of timber for profit, but though it may fail in this respect, it more than compensates in being so valuable for the two purposes above mentioned.—RICHARD PARKER, *Impney*.

CYPRIPEDIUM CONCO-LAWRE.

AN award of merit was granted to Sir Trevor Lawrence, Bart., at the February meeting of the R.H.S. for the hybrid *Cypripedium* named above, and which fig. 41 represents. It is the result of a cross between *C. concolor* and *C. Lawrencianum*. The chief beauty of the flower, which is undeniably distinct and attractive, lies in the dorsal sepal, which is well rounded, and of a greyish white colour veined with rose. The engraving well represents this feature of the bloom. The petals and lip are similarly coloured. It is to be hoped that the name given was only a provisional one, for although to a certain extent expressive it is not euphonious.

#### DENDROBIUM FINDLEYANUM.

THIS is a very useful and effective decorative Orchid. Plants growing in 3-inch pots and having nine or ten knotted or nodated stems, about 1 foot high, covered with medium-sized flowers of

delicate and pleasing appearance, are very attractive. The petals and sepals are white, shaded with delicate mauve, the lip being cream and orange and slightly shaded with mauve at the edge. The plant is of erect habit of growth, and is deciduous.

#### DENDROBIUM FORMOSUM GIGANTEUM.

This charming *Dendrobium* is a native of Burma, and blooms at the points of the current year's growth, producing racemes of four or five large, pure white flowers, with the exception of the lip being blotched with bright yellow. The plant does best grown on a piece of board, being secured thereon with copper wire and tacks of the same material. Strips of cork should be placed between the

FIG. 41.—CYPRIPEDIUM CONCO-LAWRE.

roots and the wire to prevent the former being injured by contact with the latter.

For ordinary-sized imported plants I find a piece of board (oak or deal), about 5 inches long, 4 inches wide, and 1 inch thick, large enough. Of course large plants should be given proportionately larger rafts on which to grow. The plants should be suspended from the rafters near to the glass, and be given a high temperature with plenty of atmospheric moisture during the growing season, immersing the boards to which the plants are attached morning and afternoon in tepid water during hot weather, dipping them less frequently when dull.—H. W. W.

#### LYCASTE PLANA.

THIS *Lycaste* is one of the most ornamental members of the genus. It is a vigorous growing species, with large pseudo-bulbs, and long deep green leaves. The flowers are also large, often exceeding 4 inches in diameter. They are rather showy, the sepals, in good varieties, being of a fine claret colour tipped with green, against which the smaller white petals stand out in bold relief. The lip is white with numerous small rosy crimson spots, the petals have also a single crimson blotch on their tips. The species was introduced from Bolivia by Messrs. Loddiges about 1842. A rather highly coloured figure is given in the "Botanical Register" for 1843. A fine plant is now flowering at Kew.

The variety *Cumminsi* differs chiefly from the type in having the lip wholly rose coloured. In the variety *Measuresiana* the petals, as well as the lip, are thickly spotted with crimson.

#### CELOGYNE CONFERTA.

Like many others of the smaller *Celogynes* this charming species appears to be a good deal overlooked in gardens. It is, however, really an attractive little plant, and is quite worthy of a

place in any collection. It is a very dwarf species, the pseudo-bulbs being little more than an inch in height. The leaves, which are produced in pairs, are short and leathery. The raceme springs from the base of the old pseudo-bulbs, and bears, as a rule, three flowers, each about  $1\frac{1}{2}$  inch across. The sepals and petals are pure white, but the lip has a yellow blotch in front, and the side lobes, which curve inwards, are beautifully pencilled with golden yellow.

Like *C. odoratissima*, which it much resembles in size and habit, this species requires an intermediate temperature. It may be grown on rafts, but succeeds better in small pans suspended from the roof. A compost of sphagnum and fibrous peat and a liberal supply of water at the roots are its principal requirements. A small plant is at present flowering in the cool Orchid house at Kew.—A. B.

## PACKING GARDEN PRODUCE.

(Concluded from page 170.)

IN packing vegetables, Turnips, Onions, Carrots, and Radishes are put together in one hamper; young Cabbages, Cauliflowers, and Lettuces in another, the latter being invariably uppermost, as they are easily damaged; Cauliflowers are packed between these and Cabbages. Peas, if plentiful, may be packed separately, or any space left is filled with Broad Beans. Generally Spinach is placed with Cucumbers, Vegetable Marrows, and Globe Artichokes, the latter being a vegetable which does not travel well unless carefully packed. Parsley, Mustard, Cress, Mint, and other herbs are put where space can be found for them. I endeavour to fill one hamper with flat bottomed, square punnets, in which there are Mushrooms, Tomatoes, and similar small things. A piece of paper is tied round and over each punnet. Small boxes, containing choice flowers, are packed with the punnets. It is not necessary to line all the hampers with paper, but a sheet ought to be placed on the top of the contents of each. It costs but little to do this, and the neatness secured is certainly worth the expense.

In general I think there is more care taken to ensure transmission of fruit so that it reaches its destination in good condition, than there is with either vegetables or flowers. For common fruits, such as Gooseberries and Currants, the punnets mentioned above are requisitioned. They are also employed for Melons. Each Melon is enveloped in packing material, and a punnet placed over each end; a string tied twice round keeps the punnets from moving. Grapes arrive in perfect condition, packed, as I shall describe, in a small hamper, which is first of all thickly lined with stout paper. The hamper is then placed in a sloping position, and the bunches put closely together until full. Cavities are filled with thin paper, and a few sheets of stout paper are placed on top next to the lid. At one time I used partitioned flat boxes for Peaches, but I find that open flat boxes do as well. It is not desirable to pack ripe Peaches without first swathing each in wadding. The lid of each box is tied down with string.

Regarding cut flowers, the chief points to observe are these: Select blooms which do not flag quickly or fall to pieces on the journey. Gather only those that are young, and fresh in the morning, and place the stems for two hours in clean water. There is quite a number of good flowers which cannot be depended upon to travel; some of these are Pelargoniums, Spiræas, and Mimulus. The blooms of double Ivy-leaved Pelargoniums, which are so pretty in vase decorations, even when gummed cannot be depended upon to hold together. It is, therefore, wise to reject all flowers about which there is any doubt whatever. Unfortunately, it does not always rest with the gardener to select, and occasionally special flowers are asked for, and these, no matter how unsuitable, must be sent. However, it is satisfactory that very many choice flowers are suitable, and these ought to be preferred. The propriety of choosing only young blooms is apparent when it is considered that they are superior to old ones; they arrive at their destination in better condition, and they last longer. The blooms of many plants are, indeed, better cut before they are fully developed, and all such ought to be chosen at the latter stage. A select list of such comprises Tulips, Narcissi, Irises, early Gladioli, Sweet Peas, Arums, Rhododendrons, Pæonies, Roses, Anemones, Eucharis, and Lilies; also some Orchids, as, for example, Dendrobiums. Orchid flowers ought to be cut when newly opened. During hot weather blooms apparently fresh fade quickly if left too long a time on the plant. Soaking the stems in water is beneficial from the fact that the cells are by this means charged with water, and the flowers consequently keep fresh much longer. Generally speaking, it is unadvisable to sprinkle water on flowers. If the atmosphere is dry and the weather hot, it is a better method to dip the boxes in water. Sometimes instead I place a layer of wet paper underneath, and then between it and the flowers one or more sheets of dry paper.

An essential part of good packing is to do it so that blooms are neither crushed nor bruised. The medium between too close and

over-loose packing is arrived at alone by practice; but whilst that is the case there are methods which obviate much of the evil effects of either. One of these consists in tying flowers in bunches. A few kinds are not amenable to bunching, but mostly all good flowers are. Short-stemmed blooms require only one tie, those with long stems two. All the flowers in each bunch must face one way. Three to six Arums make a bunch, six of Emperor Narcissus, and twelve blooms of the poeticus section. The foliage of some plants is best tied with the bloom; in this way Lily of the Valley, Tulips, and Roses are arranged. Previous to any flowers being placed in the box or hamper, the receptacle is lined with stout paper. There is no better available non-conducting material than paper, hence its value. Fine thin paper is employed to pack among choice flowers. Such a difficult flower as the Eucharis travels safely with nothing but this fine paper placed between and above the petals. Light boxes and hampers are tied in twos and in threes; but in no case is one parcel made too heavy or too bulky for rapid handling.

The plants invariably sent to "town" are foliage kinds only. When tall they have to be packed in a slanting position to enable them to pass under viaducts; large plants are always heavy, and the only means of sending these without receiving damage is to pack securely. Here, also, paper is solely used. If a Palm is sent a stout stick is first put in the pot, to the stick all the leaves are tied separately, and paper is then wound firmly round and tied on. Plants of *Ficus elastica* do not require the foliage tied; beginning at the base of the plant the leaves are pressed close to the stem, and are kept there by means of sheets of paper, which when put on are tied in a few places. *Aspidistras* and Maidenhair Ferns are examples of plants which as a rule are sent without being first tied up in paper. Strong crates are used for carrying purposes. The plants are first of all packed closely together and the pots protected by means of straw. Then the larger plants are tied together and the smaller ones in turn secured to these. Packed in this way they arrive at the end of the journey in perfect condition.—R. P. B.

## PROTECTING FRUIT BLOSSOMS.

THE casual observer cannot but have noticed that there is a great difference in the bearing of fruit trees. This may be due to various causes other than variety, as location and culture, for the blossoms of fruit trees vary in hardiness. Large flabby blossoms on young sappy wood are more liable to suffer from frost than sturdy flowers borne on well matured harder wood; in fact, adaptation of a variety to the environment depends greatly upon acclimatisation and cultivation. If an Apple tree is planted in rich, deep, damp ground on the flat, and another of the same variety is planted wholly above the surrounding level, there is a difference in the hardiness of the blossoms of the two trees. Those of the tree placed in the level ground are perhaps larger, thinner, and softer in texture, expand widely to receive and condense aqueous vapour into dew, which soon passes into hoar frost, and the consequence is they are easily crippled or destroyed. On the other hand, the blossoms of the tree on the mound are bold, sturdy, and leathery; not being succulent, the invisible moisture of the atmosphere is not condensed quickly by them, because they are comparatively warm and dry. The cold causes the nerve-like ducts of the cells in the petals to contract and fold over the organs of fructification, which encloses relatively warmer and drier air, so that less dew is deposited on the blossoms, and they longer and better resist frosts. In brief, cultivation has an important bearing on the hardiness or otherwise of fruit tree blossom. Varieties, however, vary in hardiness of blossom. Breda, Royal, and Blenheim Apricots are hardier as trees and in blossom than Moor Park and its varieties; whilst the Syrian variety, Kaisha, sets and brings more fruit to perfection in a given space than any other Apricot. There is no Cherry so hardy in blossom as Corone (Hertfordshire Black), and its petals hug the stamens and pistil on a cold frosty night.

The difference in the hardiness of the blossom of Pears is remarkable. Crawford, Lammas, Hesse, Beurré Capiaumont, Fertility, and Swan's Egg may be less gaudy than most varieties when in bloom, but they are generally loaded with fruit when Williams' Bon Chrétien and others have the merest sprinkling. Comte de Lamy produces sturdy blossoms at the points of the well-set growths, and it is not only the best flavoured of all Pears, but the most certain constant cropper. It is much the same with Plums, Rivers' Prolific defies the elements that causes Orleans to cast its frosted fruit in shoals; Victoria is burdened with fruit where Goliath and Prince of Wales collapse. In Apples there is no comparison of the tender blossomed with the hardy.

There are differences, therefore, in the hardiness of fruit tree blossoms; they may be slight, yet sufficient to account for failure

in some cases, and to point how success has been achieved in others. A tree that has to struggle with adverse climatic conditions, attended by hosts of insect and fungal enemies, cannot possibly succeed as well as another more befitting the position. Cultivators that note the natural fitness of things, Nature's selection, and, being guided by experience, proceed on like principles in their culture, cannot fail of a large measure of success. Those, however, that will cling to Nature's rejections, insist on attempting to cultivate varieties that experience has proved unfitted to open air culture, must be prepared to afford them protection against adverse climatic circumstances, either by growing them in forms available for it, or against walls or under glass.

Relative to the protection of fruit tree blossoms, it may be observed that none is altogether frost proof. The late Mr. J. R. Pearson held that dryness was the chief thing to aim at in protecting blossom from frost, and advocated open glass sheds as sufficient for those of the Apricot. Of such I have no experience. Perhaps the Messrs. Pearson will kindly say if the system is now practised and with what results. I have, however, found Apricot blossoms to endure frosts against cottage and farm house walls that were unprotected, and come out of the ordeal unscathed, whilst those on trees against a garden wall, and with a double thickness of herring netting over the trees, were blackened and the young fruit parboiled. This can only be accounted for by the projecting eaves and the greater warmth and dryness of the cottage and farm house walls preventing the deposition of dew, consequently the better resistance of the blossoms to frost. I have also observed that when a garden wall had a projecting temporary coping of wood or glass, and the netting was suspended from its outer edge, reaching to within 18 inches of the ground, that the blossoms were quite safe when those of trees similarly protected, but without the coping, were seriously damaged. This demonstrated the importance of dryness, and I found it applied to all fruit tree blossoms. Some gardeners do not believe in walls for Apricots and Peaches or Nectarines, alleging that Pears and choice Plums are more suitable for south walls; but Pear blossom appears so early in such positions, that, without protection, they are not more certain than Apricots, Peaches or Nectarines. I am not going to discuss the question of aspects, but it is as well to know that a Jargonelle Pear tree on the south side of a wall may be fruitless, whilst another on the north side is loaded with fruit the same season. Much depends on seasons and circumstances, though one thing is certain, that expanded blossoms must have protection from frost if fruit is to be had with certainty. There is no question as to the value of something projecting at the top of the wall at blossoming time. It may be only that of a few inches of slates or tiles with guttering to carry off the roof water of a building, and thus it will keep the wall dry a considerable way down. I mention this because it is worth knowing, that the ends and sides of houses and other buildings are better adapted for choice fruit culture than garden walls in many localities. Such Pears as Jargonelle, Triomphe de Vienne, Louise Bonne of Jersey, Durondeau, Marie Louise, Emile d'Heyst, Pitmaston Duchess, Beurré Baltet Père, Doyenné du Comice, Glou Morceau, Beurré d'Anjou, Joséphine de Malines, Nouvelle Fulvie, and Bergamotte Esperen are reliable sorts to afford a succession of fruit from August to May. Magnate and Beurré Diel produce enormously large and good fruit.

Apricot blossoms are the first to require attention. It is wonderful what may be effected by a little trouble and expense. Some dry straw threaded through the branches and amongst the spurs, so as to form meshes about half the size of those of a sheep net, and with the ends of the straws projecting a little beyond the spurs and inclining downward, forms a good protection. Effected in a neat manner when the blossoms show colour, and left until the trees have produced enough leaves to protect the fruit, there is generally a crop of Apricots. This simple plan answers for all kinds of fruit blossoms, the straw being excellent for placing over the roots as a mulch when removed from the trees. Another excellent method is to procure small twiggy branches of Hazel, Hornbeam, or Birch, and place them in behind the main branches of wall trees so as to hang over the blossoms, but not to unduly rest upon them, and only sufficiently thick to form a net-like covering. These are better than Spruce and other evergreen branches, though the latter are good when they do not exclude too much light. A third method is to procure some stout poles, long enough to reach the top of the wall beneath the eaves or coping when set a few inches in the ground 18 inches from the foot of the wall to keep them steady. Then make some soft straw or coarse haybands, with plenty of ends sticking out, and place them across the poles (fixed about 6 feet apart) longitudinally, the first just clear of the eaves or wall coping, the next 6 inches lower, the third 9 inches from the second, the fourth 1 foot from the third, and so on to 18 inches from the ground. The bands should be drawn

tight, secured to the poles, and made fast at the ends. The object is to keep the hoarfrost on the bands, where it may be thawed in the morning by the sun instead of on the blossoms.

Espalier trees may have Scarlet Runner stakes thrust into the ground on both sides, crossed and tied about 1 foot above the trees, a stout feathery straw band run along the forks directly over the espalier, and then similar bands at the sides, as described for wall trees. Pyramids and bushes can have poles or stakes thrust or fixed in the ground around them, so that when their upper ends are brought together and tied they will be clear of the trees. If the trees are in lines, the stakes or poles should be set parallel with the rows and meet over the centre, placing a rod lengthwise and resting in the fork so as to form a ridge piece. Straw bands may then be wound round the stakes, and at the distances named for those against walls. Trees in continuous lines should have a stout straw band fixed along the ridge, and the bands at the sides disposed as advised for placing across the poles in front of wall trees. Another plan of protecting bushes, pyramids, and espaliers is to place untrimmed Pea sticks around or along both sides, and arched over the trees, meeting or overlapping; and this simple method surpasses opaque material kept constantly over the trees. If the Pea sticks are twiggy, as Hazel and Hornbeam are, no further protection is needed unless the weather is exceptionally severe.

Straw mats secured to a light wood frame and that to poles, as advised for straw bands, are excellent for low walls or espaliers, using them only at night or during the prevalence of frost in the daytime. Close protective material must not reach entirely to the ground, but be kept fully 1 foot from it. Light awnings of tiffany, brown hessian, or scrim canvas, kept clear of the blossoms by stakes at the sides or around bush, pyramid, or espalier trees, with laths at the top to form the roof, afford needful protection. The sides may remain covered until it is necessary to remove the material altogether, but the top part must be withdrawn on fine days and when the weather is mild, an opening at the top and bottom being necessary to admit air.

Gooseberry and Currant bushes may be covered with tiffany or scrim canvas, but not reaching to the ground, and the material is easily kept in position with string secured to pegs driven into the ground. A little dry straw spread over the bushes when severe frost prevails, will afford the needful shelter and prevent the injurious effects of sudden thawing.

I will now return to wall trees. Copings have been alluded to, but I may reiterate for elucidation. A  $\frac{3}{4}$  inch board, 11 inches wide, fixed immediately under the wall coping to iron brackets slightly inclining outwards, answers for a wall of 10 feet high or less, one 14 inches wide is better for a wall 12 feet or more in height, and with a single thickness of pilchard or double herring netting in front of the trees, kept at a safe distance by poles, afford the needful protection to all but the tenderest blossoms. The netting and the coping boards should be removed when danger from frost is past. Glass coping projecting 2 feet for a 10-foot wall, and 2 feet 6 inches for a 12-foot wall, afford valuable shelter to blossoms and improve the fruit in cold districts. There are various forms; some are fixed to the wall, and the glass is easily taken out, others are "reversible," so that they can be withdrawn by day or when rain falls to wash the trees and moisten the border. As a rule it should be removed in the autumn and replaced when the blossoms need protection. Netting should be suspended from the front, and be kept clear of the trees.

For the protection of choice wall fruit tree blossom woollen materials, as worsted netting or frigi domo, are slower cold-conducting mediums than scrim canvas or brown hessian. Although I have used all these and many other substances, and prefer quarter-inch mesh wool netting, there is no objection to ordinary canvas or other material that may be sewn together and so made available. All points, however, considered, and material having to be purchased, scrim canvas No. 3 is the most serviceable for Apricots, Peaches, and Nectarines, No. 2 for other trees on south walls, and No. 1 for those on east or west walls. It must be kept from the blossoms. I use sawn larch poles 2 inches square (other kinds will do as well, only larch are the most durable), and place them 6 feet apart, the top resting under the coping, and the bottom let into the ground sufficiently to prevent displacement, 18 inches for a 10 feet, and 2 feet for a 12 feet, from the wall. At 2 feet from the ground a hole is bored with a half-inch auger in the outer face of each pole, driving in a hardwood peg projecting 9 inches forward. These support the canvas when lowered. A line of sash-cord is attached to one edge of the canvas opposite each pole, which has a stout ring with a staple near the top, so as to let the ring hang loose. Through this ring the line is passed from the under side for pulling up or letting down the canvas. Pulleys are better than rings, but cost more, yet it is saved

ultimately by the cords lasting longer. The necessary width of canvas must be sewn together, and a binding of small cord at both edges adds to its strength and durability.

Protection must commence with the appearance of the blossoms. The canvas should be drawn over the trees in the evening before the moisture descends, and it should remain in the morning until the frost has departed, then be let down to rest on the pins. Thus it is kept dry instead of lying on the ground. The protection should not remain over the trees by day unless the weather is frosty and the sun obscured. When the weather is mild it should remain down, for needless protection makes the blossoms, young fruit, and foliage tender. But the sheltering material should be retained for use when needed until the season is advanced, the weather genial, and the leafage of the trees abundant, as the young fruits are liable to injury, and crops of Apricots, Peaches, and Nectarines have been ruined even after the blossoms have been preserved, sometimes in late May. With due care the canvas will serve many years.—G. ABBEY.

## A PROFITABLE INDUSTRY.

### CRYSTALLISING FRUITS.

OF the many methods of preserving certain fruits for sale, none can possibly be so profitable as that of icing Apricots, Green Gages, Cherries, small Pears, and Angelica. At present the French seem to enjoy a monopoly of this industry, though it is to be hoped such will not be the case much longer. It may be urged that in France there are fewer bad fruit years than in England, but there is, as I shall prove, little or no force in this objection. In the first place it is doubtful if a complete failure will ever again be experienced in this country. Of late years such enormous numbers of fruit trees and bushes have been planted in well selected varieties that a bad failure seems almost out of the question. Partial failures there may be, but with so many sites chosen a general failure is not likely to occur. Lord Sudeley, for instance, did not mass all his trees and bushes at Toddington, but rightly decided to distribute the orchards over valleys and hills. Some seasons favour the trees in one locality only, and some, it may be, in all three; but enormous as may be the produce obtained from these orchards in years of plenty, there is no waste. Last season very few of us were prepared to learn that Plums were very abundant in Gloucestershire, Worcestershire, and elsewhere, while Cherries, by all accounts, were never more plentiful in Kent.

These facts are "ancient history" to many of my readers, but I have enlarged on them in order to dispose of a suppositious objection to my plea for an intelligent start being made towards establishing the most profitable industry connected with fruit culture. Even supposing our climate cannot always be relied upon to produce the requisite supplies of fruit for crystallising, what is to prevent the importation of Apricots and Green Gages, more especially on a large scale, whenever failures occur in this country? They may not equal home produce in quality, but they are the same as are imported already encased in sugar, and they are always far too cheap to please home growers of the same class of fruits.

A 1 lb. box of crystallised fruits assorted or in separate kinds cannot be bought for less than 1s. 6d., this being the store price for medium quality only. The better brands, as sold by the leading Italian warehousemen, are considerably dearer, partly owing, doubtless, to the greater profits obtained by the retailers. Even supposing the manufacturer, if I may so term him, does not get more than 1s., or, more likely, 1s. 2d. per lb., this must be a very good return. Remember the weight is largely made up of sugar, and the best loaf sugar can be bought in large quantities for less than 2d. per lb. Imported Green Gages can be bought retail at 6d., and very much less wholesale per lb.; Apricots realise rather more, but then they are also sold again at dearer rates after they have been iced. If the start was made other than in Kent, the best county for Cherries, the greatest difficulty would be experienced in procuring the requisite supplies of these, as only perfectly sound fruit is fit for the purpose.

Angelica will grow anywhere, no great cultural skill being required in raising a large number of plants from seed and growing these to a size large enough to provide stems or hollow stalks for cutting up into lengths for candying. The price obtained for this when properly prepared falls only a little short of that given for the fruits named, and it must be a profitable item. There is, then, nothing to deter anyone from starting this very remunerative industry, though it ought really to be established in connection with a fruit-preserving and bottling factory. I fail to see that any

great amount of skill is required in crystallising fruits, any ordinary cookery book giving trustworthy recipes. In some they may be found under the heading of Green Gage Glacés, Crystallised Apricots, Iced Cherries as the case may be, all, if I am not greatly mistaken, being much the same thing. The processes in the case of Green Gages consists of pricking each particularly ripe Plum with its stalks intact all over with pins. They are then put in copper preserving pans, containing clarified boiling syrup, and kept just off the fire, in which position they are left till next day, when the syrup is drained off, boiled, and returned on to the Plums again, and covered with Vine leaves. This is repeated three successive days, after which the fruit should be drained free of the syrup, placing them on wire drainers for the purpose, and put in a screen to dry. After this they ought to be dipped in some prepared sugar, which has been boiled to the "third degree," whatever that may mean (and which must be worked slightly with a spoon to dull it) and placed upon a wire fruit drawer resting on a baking sheet. At the end of about ten minutes, if the sugar has been properly boiled, the fruit may be detached without breaking the sugar by pressing with the fingers from underneath. Apricots are usually split and peeled, and not pricked. In all other respects they require the same treatment as that recommended for Green Gages. Small Pears only are candied, these being smoothly peeled but not cut or pricked, and otherwise treated similarly to Green Gages. Sound ripe Cherries should be selected and the stones picked out with a pointed stick without bruising the fruit. In other respects treat similarly to the other fruits, only the Cherries ought to be turned occasionally while being dried in the screen.

Preserving Angelica green would appear to be almost a lost art in this country, though a revival is taking place in two instances that have come under my notice. I can only find one good recipe, and that is by Francatelli, and which, perhaps, I shall be allowed to reproduce in full as follows:—"Cut the tubes or stalks of Angelica into 6-inch lengths, wash them, and put them into a copper preserving pan with hot syrup; cover the surface with Vine leaves, and set the whole to stand in the larder till the next day. The Angelica must then be drained on a sieve, the Vine leaves thrown away, half a pint of water added to the syrup, in which, after it has been boiled, skimmed, and strained into another pan, and the copper pan has been scoured clean, both the Angelica and the boiling syrup are to be replaced and the surface covered with fresh Vine leaves, and again left to stand in this state until next day. This process must be repeated three or four days running, at the end of which time the Angelica will be sufficiently green and done through, and should then be dried and otherwise treated as advised in the case of the fruits already alluded to. Or if preferred the Angelica tubes may be put into jars without breaking them. After the syrup has been boiled and skimmed fill up the jars, and when they are become cold cover them over with bladder and paper, and store in a very cool temperature."

I ought, perhaps, to add that the proper way to prepare the syrup several times mentioned is as follows:—"To 3 lbs. of loaf sugar add 1 quart of water and half a white of egg; whisk all together in a stew pan or sugar boiler, and set it to boil gently for five minutes, adding occasionally a little cold water, and then strain it through a napkin into a basin.

To the male mind the foregoing brief outline of the process adopted in crystallising fruits may appear somewhat formidable, but this is an industry that females are best adapted to, and a fairly large undertaking should find employment for a considerable number of respectable women.

What greatly adds to the appearance and consequently the market value of these fruits are the very showy boxes in which they are neatly packed. At Christmas time these boxes of French fruit are very freely distributed in the form of presents by leading grocers and Italian warehousemen—they would almost appear to have been invented for that very purpose. Now, if there was a demand for this class of box there would be plenty forthcoming, made in this country too. It would really be a relief to very many English people to see more of our products in the markets, "Made in Germany" being repeated far too often to be pleasant reading. I happen to know that very cheap flat or circular paper boxes with showy pictures on the exterior and equally ornamental accessories for the interior could be had from Bristol, and doubtless from various other large towns. Filling the boxes again would be best done by females. It may be asked how the fruit is to be sold to best advantage after it is ready for the markets? The same large wholesale firms who take much of the jam that is made would be equally ready to pay a fair price for good English crystallised fruits, and that would most probably be the best method of distribution open—at any rate for some time to come.—W. IGGULDEN.

## ROSE SHOW FIXTURES IN 1893.

- June 20th (Tuesday).—Westminster (N.R.S.).  
 „ 28th (Wednesday).—Clifton,\* Richmond (Surrey), and Windsor.  
 „ 29th (Thursday).—Eltham.  
 July 1st (Saturday).—Crystal Palace (N.R.S.).  
 „ 4th (Tuesday).—Canterbury and Gloucester.  
 „ 5th (Wednesday).—Croydon, Ealing, and Lee.\*  
 „ 6th (Thursday).—Bath, Norwich, and Sutton.  
 „ 11th (Tuesday).—Wolverhampton.†  
 „ 13th (Thursday).—Worksop (N.R.S.), Harleston, and Wood-bridge.  
 „ 14th (Friday).—Helensburgh.  
 „ 15th (Saturday).—New Brighton.  
 „ 27th (Thursday).—Southwell.

\* Shows lasting two days.

† Shows lasting three days.

I shall be glad to receive the dates of any Rose Shows not mentioned above for publication in my next list of fixtures, which will be issued early in April.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## NATIONAL ROSE SOCIETY.

I HOPE that I may be excused for interfering in the little tournament now going on in the pages of the *Journal of Horticulture* between Mr. Pemberton and Mr. Grahame, of which I think we may now say to both combatants, Hold, enough. Of course, I think it was a pity that the main question should have been shunted off the line and the issue joined on a side matter which had, as I believe most rosarians think, nothing to do with it. I am sorry that Mr. Pemberton took the line he did in his attack on Mr. Grahame, but I do think we may ask that you would kindly interpose your editorial fiat and say the “incident is finished,” as the diplomatic phrase runs. Both are well accounted of in the Rose world—one as one of our most successful exhibitors, the other as one who has done good yeoman service for the N.R.S., has procured a large number of members, and has induced the Society to introduce the new system of exhibiting according to amount of Roses grown; therefore I say to both, Bury the hatchet, and if they are still thirsting to scalp each other I hope you will promptly take it from them and bury it yourself.—D., *Deal.*

## NATIONAL ROSE SOCIETY—THE ROSE CONTROVERSY.

WHAT was my horror on opening the *Journal* this week to find that the apparition I thought laid, had again arisen to haunt me from the dank Essex marshes! It has struck me that the following short and hitherto unpublished extract from the drama, entitled “The War in the Rose World,” best explains how the “Veracity” case stands.

## DRAMATIS PERSONÆ.

The Very Rev. P. (*Bishop of Havering*), a proud rosarian of ancient fame, and a leader of men on clay.  
 Sir C. J. G. (*of Coombe*), a Surrey knight of some slight renown.  
 And OTHERS.

## ACT. V.—SCENE 4.

Scene—*Somewhere near London.*

(*A battle is raging in the distance, and from out the mêlée two knights are seen to separate themselves and approach.*)

Very Rev. P.—Hold and stand fast, impostor! Thou sorry knight and ignorant novice of '89. What canst thou know of Roses? Defend thyself!

Sir C. J. G.—Softly, good sir, softly; although, mayhap, not quite so old a hand or doughty champion as thou art, yet perchance I may be granted an earlier year of birth—even say that of '73.

Very Rev. P. (*in a musing*).—Ah! “IF” this were true, then it were possible I might apologise.

Sir C. J. G.—Most reverend sir, even with your reserved “IF,” I would accept your withdrawal, and without reservation.

Very Rev. P. (*suddenly becoming enraged*).—No, false knight! Thou daredst to doubt my veracity, so here's at thee! (*Deals Sir G. a foul blow, who at once collapses, and is carried off the ground.*)

[Band plays “The Bogey Man.”]

## TABLEAU.

N.B.—The influenza and the effect on many of a severe Lenten diet at the moment accounts for many hallucinations.—CHARLES J. GRAHAME, *Croydon.*

[We think, as “D., *Deal*,” suggests in his letter, that the time has arrived for dropping the curtain.]

## THE WINTER AND TEA PROTECTION.

WE may now hope to have seen the last for this winter of really severe frost sufficient to be fatal to Tea Roses, and in the eastern counties we have certainly been more leniently treated than in the two previous seasons. I am becoming more than ever convinced that elevation—a high position—is the most desirable precaution for avoiding injury

to Tea Roses from frost. I have now some Tea standards on the very highest point in my grounds, and though only protected by a little Fir branch or two, even the protruding tips are unhurt.

With my Tea standards on the lower ground, where they have suffered so severely in past winters, I took severe measures, determined they should not be killed if they could be kept alive. So I dug under one side of each row, and bent and pegged the plants down on the other side flat on the ground, and covered them, first lightly with straw and then with 6 inches or so of mould, they were thus clamped like Beet or Mangold. My *Maréchal Nels*, the few I have left, were treated in the same way, but, of course, I do not know yet how the poor things like it.

For my Tea buds—standard stocks budded last summer with Teas—I found what I believe will prove to be a capital protection in the straw cases used by wine merchants for covering the bottles they send out. The budded laterals must of course be cut rather short, but you may leave a wild bud or two beyond the “work” and yet have room to slip these useful nightcaps over their heads far enough to prevent their being blown off. It is desirable to see that the top string of each one is as tight as possible, and then this covering seems to have the following advantages: It requires next to no preparation, is on and off and on again in a moment, and makes no litter; acting as a thatch it keeps the bud dry as well as warm; and, lastly, I have no doubt they can be procured in quantity very cheaply at hotels and clubs, if something be offered for the collection beforehand.

## RETARDING TEAS.

I wonder those exhibitors who complain about their Teas being all over by the time of the principal shows do not try some methods of keeping them back. The north side of a wall will not do, for Teas do not like shade, and too late pruning will not do either, or the plants will have spent too much of their strength. Years ago, when I lived in a higher situation and grew Teas better than I do now, I used to retard mine by the simple process of mulching heavily. Mulching is commonly used in the autumn to keep plant roots warm, but it should not be forgotten that a blanket will keep ice cold as effectually as it will keep a man warm. My mulching, not less than 3 or 4 inches, of long wet manure was put on in late winter when the soil was thoroughly chilled, and kept on till the last, and I believe it was successful, but the plants being more backward did not, of course, look so strong as others in May, and one is apt to be dissatisfied at that time. Still, there was no Tea Rose show in those days, and then as now, the man who had good store of first bloom Teas well into July had a great pull over his rivals. If anyone feels inclined to try it, I should recommend the experiment being tried with a few at first.

## THE GRECIAN PRUNING SAW.

I have been surprised that I could not get any of the ironmongers in the large town near which I live to understand what I meant by a pruning draw-saw of the form known as “Grecian.” It is a very simple saw, yet always seems to me the best and handiest instrument for cutting through large roots in the ground without moving the soil. I have got one again at last from a large firm of seedsmen, and to-day, being too cold for any other job connected with Roses, I sallied forth to my old trade round the hedges of collecting standard Briars. The saw was new and sharp (it is apt to get soon blunted in sawing through the soil), and it was astonishing what quick work it made of getting strong stocks out of cramped positions in thick hedges without injuring the roots. With a little single-hand stock axe for removing the earth, a large strong pair of pruning scissors for branches and small roots, and the Grecian saw, I had twenty-nine good Briars in a little over two hours, and felt I had earned my dinner. Root-pruning of fruit trees is not often required on my soil, but I should think this would be the best instrument to use in such cases, though of course the cut part should be afterwards pared with a sharp knife.—W. R. RAILLEM.

## DISCUSSION ON PEACHES.

## PEACH CULTURE INDOORS AND OUT.

WHERE ripe Peaches are wanted at midsummer the forcing should have commenced in January, and in such cases the opera or must proceed cautiously. Do not maintain too high a temperature to begin with; 45° at night with a rise of 5° by day should be the maximum until the buds begin to open, when a higher temperature will be necessary. The borders must receive a thorough soaking of tepid water so that they will require no more while the fertilising is going on, as the fruit will set better in a dry atmosphere than in a humid one. Air should be given on all favourable occasions, and the available surfaces damped only on the mornings of fine days until the fruit is set. In forcing Peaches thus early I find a camel's-hair brush the best fertilising agency; the flowers should be gone over daily with it at about noon, or as soon as the pollen is dry. It is rather tedious work, but it pays for doing; on fine dry days the pollen can be dislodged by giving the tree a sharp rap with the hand. When the fruit is set the forcing can be hurried on for a time provided the weather is favourable, but the trees have yet a critical period of stoning to pass through, and here again caution must be our guide. Let the temperature be steady; 60° at night with a rise of 10° by day. Previous to this the fruits should have been thinned to the number that is required to be left on to ripen. Keep the roots well supplied with water, also use the syringe frequently on the trees until the fruits begin to ripen, when it must be reduced until after the fruit is gathered.

It has been said, and there is much truth in the assertion, that good

Peaches can be grown without the aid of glass houses; but this remark only applies to places where the soil and situation are favourable to the growths of the trees. In some localities it is impossible to grow Peaches out of doors; therefore, it is absolutely necessary that in such places they should have the protection of a glass house. One of the best examples of outdoor Peach culture I have seen is at Cardiff Castle, and there, with a combination of cultural skill and a good situation, the trees produce some splendid fruit; there also is some of the finest specimen trees indoors that I have ever seen. Trees that are growing too strong or rooting deeply into bad soil would be better lifted and have their roots placed nearer the surface in a good compost. The work could be done any time between now and the third week in March, as Peach trees will respond to late planting better than any other fruit trees.—R. MORSE.

#### PEACHES AT THE BRIARS, REIGATE.

EXCEEDINGLY interesting to all concerned in Peach culture is the house at this place which is devoted to these fruits and Nectarines. It is a span, fairly high, well ventilated, and standing, as everything about the place is, on the top of a sharp slope to the east. The remarkable thing about the trees is the enormous development of stem. The trees were planted about fifteen years ago. On one side there is a very fine Rivers' Early York Peach that has close to the ground a massive stem fully 3 feet in circumference, and from it breaks out three large branches from 6 inches to 8 inches through. The entire tree covers an area 24 feet by 12 feet, is trained on a trellis 3 feet from the glass, and carries enormous crops. All the other trained trees have relatively the same huge stems and robust growth. They comprise Princess of Wales and Noblesse Peaches, Lord Napier and Humboldt Nectarines.

Mr. Bailey remarks that heavy cropping is absolutely needful to keep the trees somewhat in check. The borders are about 4 feet in width, but it is evident the roots have gone away into the natural soil, which is a very good dark loam on stone brash, with a chalk strata below. In the centre of the house are several very fine, but still clump-headed, standards having most massive stems. These are about 12 feet in height, and comprise Stanwick Elruge and Lord Napier Nectarines, and Early York and Princess of Wales Peaches. There is at one end on the side border standing a huge standard of Early York in a large pot, the roots of which have gone through into the border.

Altogether it is a very remarkable Peach house, and when in fruit must present a beautiful sight. The borders are now mulched with manure, a combination from the stable, cowshed, and pig-stye, well mixed and prepared. This gives some food for surface roots, and emits a little welcome ammonia.—A. D.

#### ALEXANDER AND WATERLOO PEACHES—BUDS DROPPING.

I DO not know what may be the experience of other gardeners this season with the culture of Alexander Peach, but once again has it been my misfortune to see all the best and most promising buds drop just at the time when one naturally expects them to expand into bloom. The only flower buds which have not dropped were the terminal and spur buds, of which there is a good set. I enclose samples for your inspection. Knowing from practical experience the fault of this Peach to cast its buds, I was tempted when again taking charge of these gardens last October to replace Alexander by a tree of Waterloo, but deferred doing so for the sake of one more experiment.

Gardeners assign various causes which help towards the dropping of Peach buds, but in my case none of the usual alleged faults will apply. The wood was perfectly matured and broke regularly into growth, water had been early applied in sufficient quantity to the borders, no insecticide was used, as the trees were perfectly clean and healthy, yet the buds dropped except those mentioned. This in my opinion shows that there is some constitutional weakness in the Alexander Peach, either from over-propagation or from climatic causes, as it is a well known fact that buds drop less from this American variety later on than they do in early houses. In the same border and house, which is an early one, trees of Noblesse and Lord Palmerston Peaches, with Lord Napier Nectarine, have not cast a bud, but have an abundance of fruit set and swelling.

I have come to the conclusion after careful experiment and observation during several years, that this variety requires different treatment to other Peaches. Instead of disbudding the growth it should be allowed to extend and be pinched so as to form spurs; I fully believe that therein lies the secret of success with this Peach in this country. The buds do not drop from spurs and terminal growth, but appear in clusters, and with careful fertilisation every one of such buds expands and sets its fruits. I intend to try Alexander as a cordon and hope in due course to be able to report progress.

I have grown Waterloo as well as Alexander, and after trial think the former is a far better Peach for early work than is the latter. Waterloo is of a better constitution and does not drop its buds like Alexander. The fruit, moreover, is larger, of a better colour, and quite as early. I cannot understand why Waterloo is not more grown than it is in early houses in preference to Alexander, as Peaches which ripen good fruit a month earlier than other varieties are certainly valuable, and it is of no use depending upon Alexander until its culture is thoroughly mastered when we have at hand so excellent a Peach as is Waterloo for early work. Those who have the opportunity should plant the two varieties, and they will not be long in giving the most room to Waterloo.—JOHN CHINNERY, *Downton Castle Gardens*.

[The three flowers on the terminal immediately below the central growth bud have set perfectly, as have the two on the small spur. We shall be glad to hear what other growers of the Alexander and Waterloo Peach have to say about them.]

EVENTS OF THE WEEK.—The ensuing week will be rather a busy one in horticultural circles. On Monday evening, March 13th, the annual meeting of the United Horticultural Benefit and Provident Society will take place at the Caledonian Hotel, Strand. The Committees of the Royal Horticultural Society meet on the following day March 14th, at the Drill Hall, and Professor G. Henslow will give a lecture at the afternoon meeting. The Committee of the National Rose Society and the Horticultural Club also meet on the same day at the Hotel Windsor. The first spring Show of the Manchester Royal Botanical Society will be held at Manchester on Tuesday next. The customary auction sales will take place, including the second portion of the Fernside collection of Orchids, which will be sold on the 11th by Messrs. Protheroe & Morris at their rooms.

— THE WEATHER IN LONDON.—Bright spring-like weather is rapidly bringing forward the fruit blossoms in the south, and already numerous trees and shrubs are showing signs of bursting into leaf. Sunday, Monday, and Tuesday were fine and mild, and at the time of going to press there are indications of similar weather continuing.

— THE WEATHER IN THE NORTH.—Since the opening days of March, on which much snow and sleet fell, there has been an improvement in the weather. Occasional showers day and night have occurred. Sunday was a fine day throughout, Monday also fair but colder, and this morning (Tuesday) promises well though somewhat dull. Crocuses have pushed rapidly into bloom.—B. D., *S. Perthshire*.

— ROYAL HORTICULTURAL SOCIETY.—The Society will hold its next display of fruits, flowers, and vegetables in the Drill Hall, Westminster, on Tuesday, March 14th. At 3 P.M. the Rev. Prof. Henslow will lecture on "Some Effects of Growing Plants under Glass of Various Colours," which ought to prove interesting to gardeners. All persons whether Fellows of the Society or not, may exhibit at the Society's meetings.

— UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this Society will take place on Monday evening, March 13th, at the Caledonian Hotel, Strand. The chair will be taken at eight o'clock by Geo. J. Ingram, Esq.

— ELECTRO-HORTICULTURE.—This was the title of a paper read by Mr. G. E. Bonney before the members of the National Amateur Gardeners' Association at the Memorial Hall, Farringdon Street, E.C., on Tuesday evening last. Mr. T. W. Sanders presided, and there was a large attendance. Mr. Bonney dealt with his subject in an able manner, and detailed methods by which electricity could be brought to bear upon plant culture, remarking that in some instances beneficial results might accrue from its use.

— GARDENING AT THE GORDON BOYS' HOME.—Lieutenant-Colonel J. B. Walker, Commandant of the Gordon Boys' Home, says material for the sixty-two boy amateur gardeners of the institution will be thankfully received. Their plots of ground have been dug, manured, and prepared, but plants to stock them are sadly wanting, and it is suggested that roots of herbaceous and perennial hardy plants, such as are thrown away every year by hundreds in large gardens, might instead be packed in hampers and forwarded to Woking Station.

— WE have to acknowledge the receipt of the Rev. D. R. Williamson's "POEMS OF NATURE AND LIFE," from the press of Messrs. Blackwood & Sons. This small volume is a model of tastefulness, both in binding and typography, as becomes a work emanating from so distinguished a firm. The author seems to possess a keen sense of the beautiful in music and in scenery, and to have been a busy bee in the garden of the English poets, his sweets having everywhere a familiar and eclectic flavour. We cannot instance his poems to flowers, to wit, the Snowdrop and the Primrose, as being among his happiest efforts, though here as elsewhere his muse moves melliflously enough. His best work is contained in the twenty-two sonnets of which those "To a Great Singer" "To the Sun" "To a Musician" (1) are the best. There is also a very pretty "Poem of the Sea," and a most meritorious apostrophe to the village of Killin on Loch Tay.

— **BOTANY IN HELIGOLAND.**—The German Government has established a biological Institute on the island of Heligoland, and has appointed Dr. Kuckuck its Botanical Director.

— **DEVON AND EXETER GARDENERS' ASSOCIATION.**—At a recent meeting of this Association Mr. William Andrews, gardener to Mrs. Biddell, Duryard, read an interesting paper on "Kitchen Gardening." Mr. Andrews opened his subject with a warning to young men just launching into the gardening world against the neglect of outdoor work.

— **THE MOSS HERBARIUM** of Dr. Rehmann and Hepaticæ herbarium of Dr. Gottsche have passed into the possession of the Botanical Museum of Berlin; the Botanical Museum of the University of Vienna has acquired the moss herbarium of Hoppe; and the Botanical Institute of the German University at Prague the greater part of the valuable library of Prof. Wilkomm.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 15th instant, at 7 p.m., a lecture will be given by Mr. Shelford Bidwell, F.R.S., on "Some Meteorological Problems," which will be illustrated by experiments. Fellows may introduce visitors.—WILLIAM MARRIOTT, *Assistant Secretary*.

— **GARDENING APPOINTMENTS.**—Mr. A. Drewitt, for three years foreman at Ketton Hall Gardens, near Stamford, has been appointed gardener to Mrs. Creyke, Holbrook Park, Horsham, Sussex. Mr. C. Elliott, for the past three years foreman in The Gardens, Underley Hall, and formerly at Drumlanrig, has been appointed head gardener to Mrs. Wilson, Luneville, Torquay. Mr. J. Wyke, late gardener and steward to E. P. Westby, Esq., Roebuck Castle, Dundrum, Co. Dublin, has been appointed gardener to the Earl of Clonmel, Bishop's Court, Straffan, Co. Kildare.

— **JOHNSON'S GARDENERS' DICTIONARY.**—As announced in a previous issue, a revised edition of this useful book is being published in eight monthly parts by Messrs. G. Bell & Son, York Street, Covent Garden, and the first instalment to hand shows that the work has been well accomplished. This part comprises 128 pages, and although the arrangement hitherto adopted has been adhered to, several important additions and alterations are noticeable. Many of the cultural directions have been re-written and brought up to date, whilst references as to where illustrations of many of the plants described may be found are also given.

— **WAKEFIELD PAXTON SOCIETY.**—At the recent meeting of this Society the Secretary, Mr. G. W. Fallas, gave the fourth of the series of papers on "Elementary Botany," describing the growth of plants and the materials of which they are composed. He explained how the leaves breathe in from the atmosphere and the roots absorb from the soil the necessary elements, and how these meet and are transformed in the cellular structures of the stem into the nutrition which is thus distributed throughout the plant. Mr. Fallas very lucidly set forth these intricate processes, accompanying his exposition with sketches on a blackboard.

— **THE BIRMINGHAM GARDENERS' ASSOCIATION.**—At the last meeting Mr. G. A. Bishop, gardener to S. T. Mander, Esq., Wolverhampton, and whose silver medal essay is appearing in instalments in our pages, read an exhaustive paper on "Chemistry as Applied to Gardening," and with the aid of chemical experiments, afforded much valuable information to a large number present. He especially emphasised the necessity for acquiring a knowledge of the chemical ingredients of soils, and answered a number of questions put to him. A very hearty vote of thanks was accorded Mr. Bishop for the paper.

— **A HANDSOME LEGACY.**—Mr. Hughes, the Hon. Secretary, announced at the above meeting a handsome legacy of £300, through him, to be devoted to the Association, and he is handing it over to the trustees (of which he is one) of the valuable library and other property of the Society, to be dealt with as they think best. Mr. Hughes exhibited at the same meeting a very fine well bloomed specimen of *Dendrobium Picardi*, with a profusion of closely flowered strong growths. Messrs. Hewitt & Co. of the Nurseries, Solihull, exhibited several examples of Barbe du Capucin or Chicory, fit for use, and it was a surprise to many, as they were so fine. The seed was sown early last spring, and the young plants transplanted, and grown as Seakale is. The roots were lifted early in the winter and forced like Seakale, the crowns showing great strength of growth. As a winter salad it is invaluable, and so easily grown.—W. D.

— **CHASSELAS NAPOLEON GRAPE.**—Under this name a London firm is advertising a Grape said to be a new white seedling, but no parentage is given. I have known a Grape of this name—exactly corresponding with the description given—for more than thirty years, and to the best of my recollection it formed one of a collection sent to a continental exhibition by my brother from Dalkeith well on for thirty years since.—D. THOMSON, *Drumlanrig*.

— **THE YORK GALA.**—This is always one of the horticultural features of the year, and that to be held on June 14th, 15th, and 16th, promises to be no exception to the rule. A most liberal schedule of prizes has been provided, £58 being set apart in one class for groups alone. A sum of £42, divided into three prizes, is also offered for a group of ten stove and greenhouse plants (including Orchids) in bloom, and six ornamental foliage plants.

— **IS SOOT A GOOD MANURE?**—Having heard a lecture on manure, I was surprised to hear the lecturer say that soot was of very little use, not worth fetching from your neighbours as a manure. I think that wrong, as I have seen many good changes for the better made on crops in the garden, also with pot plants; in my estimation it has a tendency to make plants grow a dark green healthy colour, and more than that it is very useful in assisting to keep down the larvæ of destructive insects. I should much like to hear some reader's opinion of the manurial power of soot.—W. C.

— **DEATH OF AN ITALIAN BOTANIST.**—We hear with regret of the death of Cav. Giuseppe Antonio Pasquale, for many years Professor of Botany in the University of Naples, and Director of the Botanic Garden. Prof. Pasquale was the author of numerous articles on botany and cognate subjects. His earliest works of which we have cognisance were on the flora of Capri (1840), and the flora of Vesuvius (1842). In 1869 he published a more complete edition. He appears to have been appointed to the post of Director of the Naples Botanic Garden in 1866, and the following year he published a catalogue of the plants cultivated there, together with a brief history of the garden.

— **LATE PLANTING OF POTATOES.**—Your correspondent "S.," p. 152, has misunderstood my remarks anent the late planting of Potatoes. What I meant was that if the sets were properly prepared it would be much better to defer the planting in gardens of any but a few for early use till about the date he mentions—the middle of April. "S." must be aware, however, that in many gardens nearly all the main crop is in the ground early in March, doubtless to save the young shoots which would otherwise be destroyed when the sets are kept in pits. That they run a greater risk from frost and other causes than if they were kept safely under cover for other six weeks is obvious. A standard authority, Thomson's "Gardeners' Assistant," advocates the planting of Potatoes as early in spring as possible, and not later than the beginning of March.—O. C.

— **THE OWLS AND THE VOLES.**—A correspondent writing from Borthwickbrac, Selkirkshire, says:—"Doubtless many of your readers will be interested to know that the mice pest has greatly diminished, if not entirely disappeared, during the last two months. The great abundance of owls, coupled with the very severe weather, has no doubt given them a check. During the severe storm last month the owls, unfortunately, suffered also. The keeper of Alemoor Loch counted over thirty of the short-eared or heather owl, and eight kestrel hawks—some lying dead, others able to fly a few yards only, while several sat until lifted in the hands. Perhaps the alternate snow, thaw, and fresh might freeze up and perish off the mice also. These short-eared owls did not go to the woods to roost, which were close to the Loch, but were in the Willows and Reeds along the edge of the Loch."

— **LEYTON AND DISTRICT HORTICULTURAL SOCIETY.**—A well attended meeting was held on Thursday evening last (2nd inst.) at The Star Coffee Tavern, Broadway, Leyton, for the purpose of forming the above Society. Mr. Fleming of Beckford Villa, Capworth Street, Leyton, took the chair, and over thirty persons enrolled themselves members. The Society consists of amateur and professional gardeners. The following gentlemen were elected as members of the Committee:—Messrs. Cornish Flatman, P. Grugeon, Cox (Secretary to the late Society), Lusby, Linnell, Sanderson, Cummings, Fells, Bull, Lane, Haywood, Miles (Treasurer of Hazlewood, Lea Bridge Road). The next monthly meeting takes place on Thursday evening at eight o'clock, April 13th. Mr. Barnes, 1, Hope Villas, Capworth Street, Leyton, is the Secretary.

— THE TOTAL RAINFALL AT ABBOT'S LEIGH, HAYWARDS HEATH, SUSSEX, for February was 3.29 inches, being 0.89 inch above the average. The heaviest fall was 0.57 inch on the 20th. Rain fell on twenty-four days. The maximum temperature was 53° on the 19th, minimum 23° on the 6th; mean maximum in the shade 46.1°, mean minimum 35°; mean temperature 40.5°, 3° above the average. Mean maximum in the sun 52°. Fruit buds and vegetation generally in a very forward condition.—R. I.

— RAINFALL IN FEBRUARY. — During February we registered 3.84 inches, having but eight dry days during the whole month. There were twenty dry days during the corresponding month of last year, when our register gave but 0.99 inch. There is a wide contrast between this month just passed as compared with that of 1891, when not a single drop of rain fell during the whole month. To those who are dependant upon the rainfall for their water supply the abundant rain comes as a boon in the early months of the year. To tree planters a wet February is always welcome.—E. MOLYNEUX.

— THE WEATHER DURING FEBRUARY AT RIPLEY, YORKS.— This month was notable for the variableness of the barometer, it rising and falling rapidly and frequently. The highest reading was 30.40 on the 4th and 5th; lowest, 28.56 on 26th; on three other occasions it fell below 29.00. The weather, as a whole, was very dull and cold, from the 4th to the 6th being foggy. Strong wind was prevalent from the 8th to the 12th. Snow fell heavily during the night of the 25th, and up to noon on the 26th, which when reduced to water was equivalent to 1.03 inch of rain. Mean reading of barometer, 29.61. Mean maximum temperature, 43.6°; mean minimum temperature, 28.9°; mean temperature, 36.3°. Total rainfall, 3.50 inches, which fell on twenty-two days; 18° of frost was registered on morning of 28th.—J. TUNNINGTON, *Ripley Castle Gardens*.

— THE WEATHER LAST MONTH — February was very changeable, without any severe frost, and but little snow in this district. It was remarkable for two very low readings of the barometer—viz, 28.76 at 2 P.M. on 21st, and 28.78 at 4 P.M. on 26th. The wind was in a westerly direction nineteen days. We had only seven bright days, one of which was clear. The barometer was highest, 30.39, at 9 P.M. on 4th; lowest, 28.76, at 2 P.M. on 21st. Total rainfall was 2.10 inches, which fell on nineteen days, the greatest daily fall being 0.41 inch on the 21st; the total fall is 0.38 inch above the average for the month. Highest shade temperature was 59° on 19th, lowest 24° on 6th; lowest on grass, 16° on 6th; mean of daily maximum 47.58°, mean daily minimum 34.43°; mean temperature of the month, 40.10°. The garden spring ran 24 gallons per minute on the 28th.—W. H. DIVERS, *Ketton Hall Gardens, Stamford*.

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, February, 1893.—Mean temperature of month, 40.2°. Maximum on the 19th, 58.2°; minimum on the 28th, 24.7°. Maximum in the sun on the 19th, 97°; minimum on the grass on the 6th, 17.7°. Mean temperature of the air at 9 A.M., 39.4°. Mean temperature of the soil 1 foot deep, 39°. Nights below 32°, in shade seven, on grass nineteen. Sunshine, total duration in month, fifty-eight hours, or 21 per cent. of possible duration. We had ten sunless days. Total rainfall, 2.66 inches; rain fell on twenty days. Average velocity of wind 13.7 miles per hour; velocity exceeded 400 miles on eight days; velocity fell short of 100 miles on one day. Approximate averages for February.—Mean temperature, 39.5°; sunshine, fifty-six hours; rainfall 1.58 inch. A mild, wet, and stormy month, with average sunshine. We have to go back to 1885 for a warmer February, and to 1883 for a wetter one.—J. MALLENDER.

— PRIMULAS IN AMERICA.—Noting your reference (February 2nd, page 92) to the *Primula* illustrations in a recent issue of the *American Florist*, allow me to state that a large proportion of the "life size" blooms shown represent the best English strains, being from seed furnished by Messrs. Carter, Cannell, Laing, Bull, and others, for competition at the Columbian Exposition.—E. L. TAPLIN-ROYLE, *Chicago*. [Granted; but the fact remains that the photographs referred to, however excellent as works of art, do not by any means represent either the vigour of plants or size of blooms that are seen in hundreds of greenhouses in the "old country," as well as in competition at shows. The very best plants portrayed in our excellent contemporary would not have the remotest chance of securing a third prize at shows where English *Primula* culture is well represented. We are great admirers of the

enterprise and cultural skill displayed in the production of many plants and crops by our kinsmen on the "other side," and we feel we are doing them a kindness in pointing out an instance of their shortcomings when an opportunity occurs, as the best method of stimulating to greater excellence—in this instance, in *Primulas*. Possibly, however, the American climate may not be so favourable to the well-being of the plants as our cooler and more cloudy summers are.]

— LILIES *versus* ROSES. — The Rev. David R. Williamson, minister at Kirkmaiden, Wigtonshire, N.B., and author of "Poems of Nature and Life," writes to us as follows:—"I have read with much pleasure Dr. Wallace's recent article upon this subject in the *Journal of Horticulture*, and I entirely coincide with his observations. I yield to no writer in my estimate of the value and beauty of the Rose, of which I have all the finest modern varieties; but in substance, purity, stateliness, and especially in endurance of fragrance and of colour, the Lily is held in greater favour with me than the Rose. I cultivate in my sheltered garden nearly all the most stately and beautiful existing species of Japanese, Indian, and Levantine Liliiums. I may add the young and gifted Duchess of Sutherland, who has recently become a great cultivator of Japanese Liliiums, recently ordered Dr. Wallace's book at my suggestion, and tells me she has been reading it with exceptional interest."

— THE BLACK CURRANT MITE. — Noticing that the Board of Agriculture are recommending Paris green for this pest, allow me to make a suggestion that I am recommending in connection with technical instruction under the Worcestershire County Council. The difficulty of reaching these mites with insecticides or poisons is that, being protected with the outer covering of the buds, nothing can reach them in the way of washes. By picking the infested buds off now (which are easily detected, and might give employment to children and women) and burning them, bushes can be cleared. I begged an infested bush some years ago, and planted it away from all others in order that I might have specimens for microscopical work. The bush was picked occasionally, and now I have none for such work, and have to obtain specimens from a long distance. The picking plan is adopted at Todington and other fruit plantations with good effects. A large garden planted with Currants a few years ago in this neighbourhood have lately been grubbed up and the bushes burnt, which the owner might with little expense have turned to good account.—J. HIAM, *Astwood Bank*.

— THE HYBRIDISATION OF PLANTS.—Dr. John H. Wilson, in delivering the concluding lecture of a series on the "Hybridisation and Improvement of Plants," given under the auspices of the Scottish Horticultural Association recently, said the difficulty attending the correct crossing of Chrysanthemums, Dahlias, and the like, was due to the minute size of the floral organs. In most Primroses dimorphism of the flowers was an aid to cross-fertilisation. The method of reproduction in Ferns was described, and the possibility of their hybridisation indicated. In reviewing the course, the lecturer said that while a very great number of hybrids had been raised, and in many cases much improvement effected from an æsthetic and commercial point of view, the field was practically inexhaustible. With changing fashions and tastes the demand for new varieties of flowers and fruits would continue. It was a mistake to fancy that the only places where new varieties could be raised were in great nurseries and botanic gardens, for first-rate work has been done in many small establishments. The successful raiser of new plants must combine a knowledge of the structure and functions of flowers with the best methods of culture of both parents and progeny.

— DIONÆA MUSCIPULA. — In the first part of the new "Contributions from the Botanical Laboratory of the University of Pennsylvania," Dr. J. M. Macfarlane confirms the statement that, to produce closure of the leaf of *Dionæa muscipula*, two distinct stimuli are required, which may be communicated to the same hair, or to different hairs on the same half, or to hairs on opposite halves of the leaf. He regards the leaf, previous to secretion, as in a state of tetanic contraction, resulting from a series of stimuli, which may either be partially or entirely mechanical, thermal, luminous, chemical, or electric. The so-called "hairs" are not true hairs, but emergences, and their structure is described in detail. Each consists of three distinct regions, the joint, the base, and the shaft. While previous observations, such as those of Darwin and Prof. Burdon Sanderson, have been made on plants of *Dionæa* under abnormal conditions of cultivation, Macfarlane's, says "Nature," are especially valuable as

having been made on the plant in its native condition ; and this is also the case with those of Mr. Bashford Dean, contributed to the Transactions of the New York Academy of Sciences. Mr. Dean states that there is a marked difference in the irritability of different leaves ; that the leaves usually fail in capturing the larger and more active insects ; that even small insects constantly escape ; and that the leaf repeatedly closes on inorganic and vegetable objects.

— THE LONG-TAILED TIT.—These are among our very best friends in orchards, and fruit growers cannot be too jealous of inter-

fered the other evening of being among our worst enemies in taking and “ knocking-off ” fruit-bloom buds. I told the man a greater mistake was never uttered. If these erroneous statements are not contradicted children are only encouraged to rob the nests of these wonderful architects.—J. HIAM.

#### BEGONIA DECORA.

THIS charming ornamental foliaged Begonia was exhibited by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, at the Drill Hall on

FIG. 42.—BEGONIA DECORA.

ference in nesting during the coming season. They may safely be said to be “ worth their weight in gold ” every year. I was recently watching a pair flitting from tree to tree, and at last one set to pecking at a small bough near the top of an Apple tree. Being determined to see what it was feeding on, I drove it hastily away, and three times it was as determined to have its dinner in defiance of me. I mounted the tree and found a large patch of moths’ eggs laid at the identical spot, about 100 packed on end in true lines, and covered with a cushion-like covering of fine hairs, apparently those of the March moth, *Anisopteryx æscularia* ; the marks left on the bark left no doubt as to the eggs having been recently taken. I again watched them and again drove one from its feeding-ground, and mounted to examine the exact spot, and found it taking the eggs of the cockle scale. I heard these birds

November 15th, last year, and the Floral Committee of the Royal Horticultural Society deemed it worthy of a first-class certificate. As will be seen by referring to the illustration (fig. 42) the leaves are medium-sized, varying from 3 to 4 inches in length, and are of an attractive character. The midribs and veins are light green, the upper surface of the young leaves being rough and bright brown, changing to a darker or chocolate shade ; the under surface of the foliage is a bright claret colour. *Begonia decora* is a dwarf growing species from Penang, and was introduced by Messrs. J. Veitch & Sons. It has creeping rhizomes, and under good cultivation the pretty marked foliage will form a welcome addition to stove ornamental leaved plants. The leaves are covered with papillæ, each of which has a terminal hair.

## RUGBY AND DISTRICT CHRYSANTHEMUM SOCIETY.

THE seventh annual Exhibition of this Society will take place on November 15th and 16th, and from the schedule to hand we observe some liberal prizes are offered.

## THE HULL SCHEDULE.

THE Hull and East Riding Chrysanthemum Society have issued a full and excellent schedule of prizes for the next Show, which opens on November 15th. Besides the 20-guinea challenge cup in the group class, with money prizes of £6, £5, £4, and £2, silver cups with £10, £5, and £2 10s. prizes are offered for twenty-four Japanese blooms, also for twenty-four incurved blooms in separate classes. An entirely new class is also provided, with prizes of £5 5s., £3, and £1 10s., described as follows:—Twenty-four blooms, Japanese, distinct, arranged for effect, and set up in any manner the exhibitor desires, with or without Chrysanthemum or other foliage, on a table space not exceeding 6 feet in length by 2 feet 6 inches in width. The object of this class is to introduce a more tasteful system of staging highly developed flowers, therefore first quality blooms are indispensable, and their merits will be estimated by points in the usual manner. At the same time artistic arrangement is essential, and will be fully considered by the judges and receive due weight in the adjudication.

## JUDGING CUT BLOOMS.

IN addition to the method of judging cut blooms which I condemned on page 180 of the *Journal of Horticulture* there is still another that I do not generally approve of, although under special circumstances something may be said in its favour. I refer to the system of attaching so much weight to the greater variety of colours that one stand may contain over its opponent. It is not an uncommon occurrence to hear that "Mr. So and So was an easy first by the greater variety of colour his stand contained." My contention is the blooms should be examined individually and carefully noted accordingly if the competition is keen, not allowing the appearance of the stand, as a whole, to have so much influence over the minds of the judges, as I fear in many cases it does.

I agree when the blooms individually are close as regards merit that the greater variety of colour should then score a point or two, sufficient to place the balance in favour; but where there exists a wide contrast in point of the individual quality, then, I think, the great leaning to the extended variety in colour is a mistake. Where the conditions of the class is clearly defined, that the prizes are offered for so many distinct blooms, then they ought to be distinctly examined and appraised according to their merit. For example, we may take a stand of twenty-four blooms in not less than eighteen varieties. No judge would award the premier prize to an exhibitor who staged the whole twenty-four blooms, distinct, simply because they were dissimilar and of inferior quality. The exhibitor who complies with the stipulated conditions of eighteen varieties, and fills the remainder of the class with blooms of high quality, even if they are duplicates, should win premier honours. As long as a competitor conforms to the expressed conditions of the class he is at liberty to employ what extra blooms he thinks best. The judges who make their awards based on this method are, in my opinion, wrong, and possess taste which shows a decided leaning to so-called artistic ideas rather than to carrying out the practical definitions that are, as a rule, so clearly defined in the schedule of prizes.

I expect to find a conflict of opinion as to the soundness of my expressed view on this phase of judging Chrysanthemums. I hope, therefore, that those persons who object to my dictum will remember that where the competing stands are close in point of individual merit of the blooms that I approve of the plan of awarding prizes for variety in colour, but not otherwise.—SADOC.

## NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of this Society was held on Monday evening last at Anderton's Hotel, when Mr. E. C. Jukes occupied the chair, owing to the unavoidable absence of Mr. Ballantine. The Chairman said he was pleased to see so many representatives of affiliated societies present, and assured them that they would always be welcome and their suggestions carefully considered. The minutes of the previous meeting were then read and confirmed, and a letter from Sir Edwin Saunders expressing thanks for having once more been elected to the presidency of the Society. The Secretary announced that the schedule for the current year was in the printer's hands, and he hoped the same would soon be ready for distribution.

The most important part of the business was the election of new members to the Floral Committee. Hitherto, it has consisted of fifteen members, one-third of whom retire annually, but are eligible for re-election. By the new rule the constitution of this body is slightly altered, there being now eighteen members, and a chairman elected from among that number. There were therefore on this occasion eight members to be elected, five to replace those retiring, and an additional three to make up the total prescribed by the new rule. Fourteen candidates in all were nominated, and as there is no rule as to the

ballot being employed, some discussion as to its legality in this instance was raised. Mr. Wright of the Temple objected to it on the ground of its secrecy, and thought members ought not to be ashamed to hold up their hands. The Chairman was of opinion that by that method no one could tell whether a member voted for more than the proper number of candidates required to fill the vacancies. Mr. Geo. Stevens moved that the votes be taken by a show of hands, but Mr. G. A. Addison made an amendment to the effect that the ballot be resorted to, and his amendment was easily carried. Messrs. H. A. Needs and T. W. Sanders were appointed scrutineers, and announced the result as follows—Messrs. C. Gibson, H. J. Jones, G. Gordon, W. E. Boyce, C. E. Shea, W. H. Fowler, H. Cannell, and E. Beckett.

The reserve fund, which stood at £14 15s. 6d. a few weeks since, has been increased to £19 9s. 6d., and the Secretary stated he would like to see the amount increased still further that evening. Mr. Fowler at once offered £5, Mr. Jones £1, Messrs. J. Laing & Son £1 ls., Mr. Harland of Hull £1 ls., and Mr. Owen £6 10s., originally intended for special prizes for new classes in the schedule. It is pleasing to record that the reserve fund was in a few minutes increased to the sum of £34 1s. 6d.

The election of Chairman for the Floral Committee for 1893 resulted in Mr. C. E. Shea being appointed. Only two names were proposed—viz., Mr. Shea and Mr. G. Gordon, the latter being defeated by one vote only. The meetings of the Floral Committee will be held at the Royal Aquarium on 6th and 27th September, 11th and 25th October, 8th and 22nd November, 5th and 13th December. The Catalogue Committee, consisting of Mr. E. C. Jukes, Mr. W. H. Fowler, Mr. H. Shoesmith, Mr. A. Taylor, and Mr. C. Harman Payne were elected, and this brought the meeting to a close.

THE controversy which has lately been going on *re* the National Chrysanthemum Society has been interesting not only to those who make the growth of Chrysanthemums a speciality, but doubtless also to others, who, like myself, take a more general interest in these matters. I have carefully read the report of the Society's last meeting, and do not feel myself able to agree with the opinion you express when you say in effect that Mr. Addison's motion for a rule providing for the expulsion of any member guilty of irregular or dishonourable conduct is fairly met by a rule which provides for the erasure of the names of members who are in arrears.

IN view of the still unanswered charges against a member of the Floral Committee *re* the Beauty of Exmouth case, and the proven charge against a member of the Floral Committee *re* the Wells case, it is abundantly clear that it is necessary some stringent rule should be made, and not only made but enforced, if the N.C.S. is to hold its position as a "National" Society. "National" characteristics are generally believed to be manliness, pluck, and upright conduct. Surely the conduct of which the member referred to has been found guilty of in the one case, and he, or another, accused of in the other case, is not deserving of any of the above adjectives; and to go still further, it does not seem too clear that the Society generally too well deserves them if it is to allow one of its members to sneak behind it under the pretence that there was danger of a libel suit. Now, forsooth, it is argued that it is difficult to decide what constitutes dishonourable conduct, and yet the member who put forward this argument would no doubt feel mightily offended if anyone should venture to cast a doubt upon his claims to intelligence. But what sensible man could have a doubt as to the want of honour in the Wells case, which has been proved, or in the Beauty of Exmouth case, if the charges are true; and that the Society should avoid putting the truth of these to the test gives to outsiders at least a strong impression of their being well founded; let me repeat the charge in case some of your readers should have forgotten it. It is stated that a member of the Floral Committee opposed the granting of a certificate to an advanced type of Chrysanthemum, and afterwards coolly informs the exhibitor that he did so because this variety would cut out one of his introduction; and he further offers to buy Beauty of Exmouth at a large price. In order to clear the Society of the slur which has been thrown upon it, Mr. W. H. Fowler suggested that the case should be fully gone into, both parties waiving their legal rights. The accuser agrees at once, the accused makes no sign; what inference is to be drawn? If the Society has gained strength by the controversy, why the bitterness with which Mr. Dean pointed out that two provincial growers who were proposed as members of the Committee had taken part in it, and suggested that therefore they ought not to be elected? As a matter of fact they were not elected.—G. MATTHEW.

BEING a reader of the *Journal of Horticulture* for over thirty years, and a member of the above Society, though not knowing any member of the Committee, I think enough space has been given to Messrs. Godfrey & Co. and the N.C.S. Committee. Doubtless, Mr. Godfrey may be right in advertising his Beauty of Exmouth, which he mentions four times on page 180.

I see Mr. Godfrey aspires to one of the National's "very best" medals. I assure him I for one will attend the meetings, and vote him a Holmes' Memorial cup, on condition that he publish the letter we have heard so much of lately in his pamphlet, so that we who are not in the "know" may judge if the best is being done by all the members of the Committee for such a good cause as the improvement of Chrysanthemums. I am sorry that some readers seem to think you favour the Godfrey-Wells side of the dispute, but I presume they are allowed to state their case, as are others to refute it.

Regarding discussion on matters horticultural, let us have plenty of

it, but no personalities; and may I ask all who have taken part in the discussion to show their goodwill towards the National Chrysanthemum Society, by subscribing one guinea to the Reserve Fund, which I see is very low; also try to attend more meetings of the Committee, and not be talked down, but press them with fact or fancies.—JAS. HAMILTON, *Byrkeley, Burton-on-Trent*.

[Perhaps the best evidence that we have favoured neither side in this discussion is Mr. Matthew's suggestion that we have expressed an opinion in favour of the N.C.S. as against Mr. Addison's motion on the one hand, and Mr. Hamilton's indication that we have favoured the Godfrey-Wells side on the other. We favour what is right on whichever side this may be found, and if Mr. Godfrey is proved wrong he will quickly find that his action will not have the sanction of the *Journal of Horticulture*; but there has been no real investigation.

This discussion will do great good, in fact we have the satisfaction of knowing on the Chairman's authority that it has resulted in the accession of strength to the N.C.S. We publish Mr. Hamilton's letter as readily as any that have been sent to us, and we fully agree with him in the desirability of increasing the Reserve Fund of the Society.

We have had expressions of opinion from various parts of the country approving of the manner in which this discussion has been conducted, and we cite a few lines from the letter of a Liverpool correspondent as fairly typical of others from districts in which the discussion was regarded on its merits alone. "The straightforward way in which you have dealt with the Godfrey and other cases has earned for you hearty commendation from your numerous readers of the *Journal* here."

That is sufficient; and now that both sides have been heard fully, and as Mr. Godfrey has announced his intention of publishing in "book form" the correspondence at his disposal bearing on the whole question in dispute, perhaps it would facilitate matters if readers who desire to express any further views would do so direct to Exmouth for the purpose of his compilation. We do not say that no further letters will be inserted in our columns, but suggest the alternative as possibly the better way of expediting the issue of the work in contemplation by Mr. Godfrey. A critique on the report and balance-sheet of the N.C.S. cannot be inserted this week.]

### GRAPES AT FLOORS CASTLE.

As I was at Floors Gardens with the late Mr. Rose, who was appointed gardener to the Queen at Windsor Castle, and also Mr. Knight, now with the King of the Belgians at Laeken, Brussels, I may tell "M." (page 117) whom I believe I know well, that in Mr. Knight's time the gardens were greatly altered and more glass erected. Vines and Peaches were increased, and for Pines a 160 feet range was erected. They are now done away with, and the houses are used for growing large numbers of choice cut flowers, such as Gardenias, Eucharis, and Carnations, which are now of greater value.

The range of houses where the unfortunate vinery was situated was cleared out by Mr. Knight, and planted with Vines from end to end in June, 1874, on the occasion of a memorable event in the Roxburghe family. The Muscats of Alexandria and Lady Downe's produced first-rate fruit, and these varieties kept well till the spring, the Muscats to March, and the Lady Downe's to May, but cutting them from the Vines in December, and leaving them in bottles on the edges of the fruit-room shelves, as also done in Mr. Rose's time. The Grapes referred to on page 31 are from the late house in this range. While in the vicinity of Kelso the other day I called at Floors, and Mr. Street kindly showed me the new Grape-room and its contents, which are certainly very creditable to him, and not at all flattered by the photograph reproduced in the *Journal of Horticulture* for January 12th. The bunches were medium sized and very large in berry, and the proper colour to keep for a long time. The Grape-room is certainly well situated and convenient, but Mr. Street takes the credit of having altered and improved the bottle-racks to hold larger bottles in better position, so that the bunches can be more readily examined all round.

As regards the remarks by "M." about the Broxmouth Muscats I may state that the same old Vine and plants from it produce prize Grapes occasionally, which are never disputed now. The large bunches never keep long, but those of smaller size, and berries well thinned out, keep in good condition the same as elsewhere.

I may mention that early Grapes were once cut on the 25th of April from an early division in the same range. Black Hamburg and Foster's Seedling were the varieties.—WM. MCKELVIE, *Broxmouth Gardens, Dunbar, N.B.*

MR. GOODACRE'S letter on the above subject in your last issue (page 172) goes far afield for "facts sufficient to show that Grapes have been successfully kept before the now celebrated room was made at Floors." I was not aware there had been any question raised in your columns as to the unsuccessful keeping of Grapes elsewhere, or that the "plan adopted" at Floors was a new one; and it certainly did not need Mr. Goodacre's "facts" to demonstrate the veriest of platitudes—namely, that late Grapes are to be found at most establishments where any pretence is made at Grape growing, and where the bottling system has been followed. What useful purpose is served by keeping Grapes in bottles for twelve months, as Mr. Goodacre relates, is not quite so apparent, unless it be someone's idiosyncrasy.

But the real object of his remarks is so ill-disguised that the only inference to be drawn from them is that he has been furnished with a brief in defence of the "plan adopted" lately at Floors; moreover

there is so much special pleading in all he says about the present gardener there and his predecessor being "pupils in succession at Penrhyn," that the irresistible conclusion is that his letter is intended to play the one off against the other.

The question as to their indebtedness to Mr. Speed's tuition for their success in Grape-keeping, or other branches of gardening, is one they will each decide as they think fit. That Mr. Speed, beside being a very estimable man, is a thorough good gardener, and that the gardens at Penrhyn are kept in a condition commensurate with his practical skill and long standing there, were, I believe, well known in the gardening world before Mr. Goodacre reflected on them the light of his genius.

But "M." (page 117) as well as Mr. Goodacre is in error in supposing there are any Vines at Floors planted thirty years ago, and consequently the latter's desire to award credit comes somewhat prematurely. There were two lean-to vineries and one side of a span-roofed house at Floors up to the time of Mr. MacKellar's leaving. That was planted, I believe, during Mr. Knight's time, but the borders of these, both inside and out, were entirely renewed by Mr. MacKellar, and for three days the Vine roots were tied up in mats without a handful of soil while the border was being cemented, drained, and re-made. The other Vines on the place were planted by him entirely.

Whether the early vinery that "M." refers to as being so unsatisfactory in his time was planted again by Mr. Knight I do not know, but it was considered so unsatisfactory when Mr. MacKellar took charge that the Vines were cut out and replanted, and it was a most successful house during his time. I should say, however, that the premature breaking that "M." speaks of was found to be a very "local influence" indeed, for it consisted in the bottom of the border being perforated with flow and return pipes connected to Orchid house and stoves the other side of it. This Mr. MacKellar had altered by substituting one large boiler for the five that originally did the work, and by forming one channel closely built in brick and cement for the flow and return pipes.—N. F. BARNES, *Eaton Gardens*.

### DOUBLE ZINNIAS.

ELDON do we see Double Zinnias well cultivated. The great mistake made is in raising the plants in too much heat, thus enfeebling their constitution. Few plants contain such a variety of colours as Zinnias, which includes all shades from creamy white to the most intense velvety crimson. In addition to their value in the flower garden, Zinnias are useful in a cut state, lending themselves to any form of decoration. The flowers keep quite fresh a long time in water. It is, however, as decorative plants in the flower garden that I think them most useful; not dotted here and there in the borders amongst other things, but occupying beds.

The first week in March is a good time to sow the seed, providing it is done in a cool frame where the growth will be slow, resulting in sturdy plants. From these satisfactory results may be expected. Sow the seed in moist, sandy soil in shallow boxes or seed pans. Keep the frame closed and shaded until the seedlings appear, when all available light should be given and air admitted cautiously, increasing it as growth progresses and the weather is favourable. When the plants are 2 inches high they should be pricked 2 inches apart in another frame. A layer of coal ashes forms a good base for the frame to stand upon; over this spread partly decayed horse manure 2 inches thick, into which the roots will run, enabling the plants to be lifted with earth adhering to them. On the manure spread sandy soil 2 inches thick, into which the plants should be dibbled. Careful watering and slight shade, combined with keeping the frame closed for a few days, will enable the plants to become established. Directly new growth is being made abundance of air ought to be given to keep the plants sturdy, drawing off the lights on all favourable occasions.

Although Zinnias like tolerably fertile soil, it must not be made too rich, or the growth will be sappy and not of the right kind to give a full crop of flowers. The soil should be deeply dug, adding, where necessary, partly decayed horse manure in the case of heavy soil; road grit and leaf mould being also valuable in this case. Where the natural soil is light and sandy, cow manure induces a robust and productive growth. Choose a showery day for planting, and put the plants not less than 10 inches apart. It is wise to peg the plants down once or even twice, a better effect being produced by having an even growth all over the bed. If the plants are inserted on the slope with a trowel, the work of pegging them down is facilitated, otherwise there is a risk of breaking the stems.

When Zinnias are cultivated mainly for supplying cut bloom it is not necessary to peg down the shoots. The ground ought to be kept free from weeds by frequent stirring with a hoe. During dry weather water in abundance given to the roots will produce free growth, and consequently a fuller crop of blooms.—E. MOLYNEUX.

### BRUSSELS SPROUTS.

"BRASSICA" (page 183) is not correct in saying that anyone successful in raising Brussels Sprouts in the open will give to anything that may be written respecting raising plants under glass scant consideration. I trust there is no gardener worthy of the name who does not recognise the great importance of dealing with climatic conditions in a sensible way; and whilst it would be folly to raise Brassicas of any sort under glass in one place it is absolutely needful to sow some kinds under glass

elsewhere. I do not for one moment recognise the assumption that because Brussels Sprouts may be raised under glass that therefore the plants are less hardy. That is too absurd.

The character of the land is in no sense changed because of such temporary shelter. Were the crop grown under glass absolutely, we could imagine that in time the native constitution of Brassicas would be weakened, but raising the seedlings under glass because of the exigencies of the position or climate, or season, which is but temporary culture under protection, is too trivial to have any weakening effect. I have seen many acres of Brussels plants put out and as hardy as any others raised outdoors, but so raised under glass because market growers have regarded earliness as of the first importance.

Brussels Sprouts, as a rule, are grown far too grossly in gardens. They should have soil deeply worked to give ample root room, but not enriched with too much strong manure and the surface should be firm. I never see in gardens such firm hardy stems and perfect sprouts as I find in the fields.—D.

For my part I think it needs but little argument to convince any person of the great advantage gained by sowing the seed under glass as compared with sowing it out of doors if they will carefully test the matter themselves. I have to-day (March 2nd) sown seed of both the varieties we grow—Sutton's Matchless and a strain of imported seed. This latter is an excellent variety to grow for those who prefer small, hard green sprouts to the extra large and sometimes coarse Cabbage-like productions.

It is useless to expect a full crop of this vegetable if the plants are not put out early; my experience is that the earlier in the season the better. A long season of growth is then obtained, and a full crop of sprouts assured.—E. M.

## SUNNY SANDRINGHAM.—II.

(Concluded from page 180.)

A NATURAL continuation to the notes on Sandringham published a week ago will be a description of the accommodation provided for the under gardeners. It is questionable if there are half a dozen places in the country where any approach has been made to the conditions which have been provided for the health and comfort of the journeymen. The range of buildings, of which the bothy forms the centre, is 230 yards long, and has been erected under Mr. MacKellar's direction. On the ground floor is a large mess room, easily capable of accommodating the twelve men who occupy the bothy, and two sitting-rooms, one for the foremen, the other, a large apartment, for the use of the remaining assistants. The rooms are carpeted and comfortably furnished, pictures adorning the walls. There is likewise a roomy kitchen with hot and cold water and a splendid range, presided over by a housekeeper, who also has rooms provided for her. Upstairs there are a dozen bedrooms, one for each man, all carpeted and furnished in a most comfortable manner. At the end is a magnificent bath-room, with tiled walls, marble slabs, hot and cold water, and every necessary convenience. The sitting-rooms are provided with grates, but all bedrooms included, are warmed by hot-water pipes cased in. It is difficult to think of any reasonable provision which has not been made for the comfort of the gardeners. They are not, as is the case in so many places, relegated to something little better than a shed, but are treated as human beings whose comfort is worth studying, and whom it is an object to train up well-conducted, orderly, and intelligent, fitted, not only by cultural skill, but by polished manners, to occupy high positions in their profession. In this, as in other matters relating to his workmen, the Prince of Wales sets a bright example to the country.

There are other parts of this new range worth referring to. Each building bears a clearly printed description, and the first is the largest of three immense boiler houses and stokeholes. It is 60 feet long and 30 feet high, of which about 15 represent the depth below the ground level. Looking down from the iron platform it is as though surveying the engine room of some great steamer, save that there are huge boilers in place of machinery. The largest, which is fitted with Thomson's patent water bars and cross tubes at the back, is capable of heating upwards of 8000 feet of piping. They have been put in and the system of heating constructed by Messrs. Mackenzie & Moncur. The quantity of piping mentioned indicates about the total length in the plant department alone. The hardness of the water led to great trouble from furring, and Mr. MacKellar has devised a plan by which the rain water falling on the sheds, bothies, and other buildings is collected, pumped into a large cistern, and utilised for feeding the boilers. It is an admirable plan and works well, the turning of a wheel by a lad doing the necessary pumping easily and expeditiously.

The potting houses (to use the familiar term shed would be to do them an injustice) are lofty, clean, well fitted, and warm. The same remark applies to the packing room. The despatch of the large quantities of fruit, vegetables, and flowers entails a good deal of work, and it has been thought worth while here as elsewhere to provide for its performance in reasonable comfort. There is a painters' room and a whitewashed and heated toolhouse, in which the implements are kept bright and clean. Then there is a magnificent Grape room, 23 feet by 16, beautifully fitted, and capable of holding 1500 to 2000 bunches. The walls are lined with and the fittings composed of best pitch pine. The fruit room is another splendid apartment. It is 60 feet long, the door, wall linings, and ceiling being all of pitch pine. This is undoubtedly one of the finest fruit rooms in the world. The appoint-

ments are not only of the best, but are beautifully executed. The same remark might be applied to Mr. MacKellar's office and seed room, with its thirty-three large drawers for seed. On opening one of them—Onions—and glancing over the contents, some idea is gained of the extent of the sowings, for there are several pounds of seed awaiting use. Altogether the range of buildings is unique, and worthy of the establishment to which it belongs.

The kitchen and fruit garden constitutes 14 acres, and is in two divisions, one within the other, each with lofty and well constructed walls. In addition Potatoes are grown in one of the fields, but in consideration of the enormous demand the surprising thing is not the extent of ground devoted to the crops, but the fact that it is sufficient. Nearly the whole of the ground is, however, double cropped. Immense quantities of the leading vegetables, such as Potatoes, Onions, Peas, Cabbages, and Carrots are needed, also of Cauliflowers, Broccoli, Asparagus, and Seakale. There are some splendid quarters of Ellam's Cabbage, some of which have already been cut, and others are hearting. Considering the severity of the winter this is worth noting, and it is a striking testimony to the value of the variety for early work. Broccoli have suffered somewhat, but Leamington and Model have come through the trying weather in excellent condition. Both varieties are highly esteemed. Forcing is extensively carried on. A good deal of Seakale is forced on the ground by autumn earthing, and quantities more, together with Rhubarb, Chicory, and others, are brought on in the large Mushroom house. There is also a range of pits upwards of 400 feet long, excellently constructed, well heated, and divided into seven divisions. These are extremely valuable for early Potatoes, French Beans, Carrots, Turnips, Lettuce, and Radishes, also accommodating bedding Zonal Pelargoniums, Chrysanthemums, and other flowering plants. Violets are also grown in them on a very large scale, and millions of flowers have been gathered during the past winter. These and other fragrant flowers are great favourites with the Princess of Wales.

At the back of the pits is one side of the new outer wall, upwards of 350 yards long, and planted with the best varieties of Pears, Roses occupying the borders in front. I should judge, from the length of wall recently erected, and the number of trees put in, that the extension of the fruit supply has been one of the great objects in view at Sandringham of late. A considerable aggregate length of wall has been built, and all has been planted with strong, healthy trees of selected varieties. Many hundred yards of espaliers have also been put up, and the system adopted is the essence of thoroughness. The strong iron supports have substantial cement foundations, containing the double elements of strength and permanency. The trees have been chosen for the same qualities. They are all developed specimens, furnished with vigorous matured growths, and set with fruit buds. Many hundreds have been planted; indeed, all available space is being filled up with the best material which skill and care can produce. The ultimate result can be safely prophesied. In a very few years the collection of outdoor fruit trees at Sandringham will be a magnificent one, fully capable of meeting the demand for fruit, and in the highest sense worthy of the establishment. Apricots have also been extensively planted, the favourite varieties being Large Early and Powell's Late. More than one wall has been entirely replanted with them. Morello Cherries, two years planted, are in most promising condition, and so are large quarters of Raspberries.

Upwards of 6000 pots of Strawberries are forced, the varieties most largely represented being Vicomtesse Héricart de Thury, James Veitch, La Grosse Sucrée, and Noble. This is a large item in itself and entails a considerable amount of work. A great extension is being made to the Peaches and Nectarines, although the collection already existing is by no means a small one. They are being managed with the greatest skill and judgment, and in due course there will be few private assortments to equal that at Sandringham. Some immense trees, full of fruiting wood, were planted last November and are thoroughly established, so that fine crops may be expected from them this season. All the Peaches on the place, and they include some gigantic old trees, have been replanted during the last two years, the borders having been remade throughout. In the earliest house the fruit is as large as marb'cs, and the trees bearing it are full of vigour.

The same bold measures are being conducted with the Vines. One large Muscat house is being entirely cleared out and replanted on the most approved principles. Muscat of Alexandria, Black Hamburg, Lady Downe's, and Black Alicante are represented in the houses adjoining the Peach range, and there are four houses in another part of the garden, the varieties occupying them being Gros Colman, Lady Downe's, Muscat of Alexandria, and Black Hamburg. The early house was in bloom at the time of my visit, and the Vines were noteworthy for their splendid foliage and healthy appearance. Another house has been planted two years, and although dormant the stout brown canes give great promise. They are upwards of an inch through, and will be lightly fruited this season. It is doubtful if a finer house of young Vines is to be found in the kingdom than this, and it speaks volumes for Mr. MacKellar's skill as a Grape grower. A house of Vines in pots also arrests attention. Thinning had just been commenced, and the plants were furnished with large, well coloured, and substantial leaves. These were raised from eyes last season, and others are just being raised in the same way to succeed them next year. This, giving due weight to the splendid condition of the Vines, represents good work indeed, and reflects great credit on the management.

A brief reference to some of the leading items amongst plants and flowers will show what a severe tax is placed on the resources of the

garden for them alone. Tree Carnations are special favourites with the Royal Family, and thousands are cultivated, including 1000 of *Souvenir de la Malmaison*. Lilliums are another immense item. Of *L. Harrisi* alone several thousands are cultivated, and they are splendidly done. Large quantities are flowered at Christmas, and many others are coming on for Easter. The extent to which these and others are grown might suggest a nursery or market establishment. Lilies of the Valley are forced to the extent of 25,000 or 30,000. *Bouvardias* and *Gardenias* are in great numbers and splendid condition, indeed one observes throughout what a great amount of attention is devoted to fragrant flowers. The quantities of *Roses*, reckoning in both those out of doors and under glass, is enough to stock many a nursery. The leading Teas, such as *Catherine Mermet* and *Niphetos*, are in very strong force. Of *Cyclamens* nearly a thousand are cultivated, together with proportionate quantities of *Primulas*, *Richardias*, *Eucharises*, *Spiræas* and *Poinsettias*; 1500 represent about the quantity of the latter. Immense quantities of bulbs are grown for Easter, and *Narcissi* are forced in thousands.

The collection of Orchids is being steadily increased, and ere long is likely to sustain a considerable development. Already the *East Indian*, *Cœlogyne* and *Cattleya* houses are well furnished, and the plants pictures of health. Palms and foliage plants also constitute an important feature. There are some huge specimens of the former for special use, and abundance of smaller plants for general decorative purposes. Perhaps it is hardly necessary to mention that *Crotons* and *Dracænas* are conspicuous in numbers, for that would be expected, but it may be added that they are in the perfection of health and colour, and a note may also be made of the fact that *Smilax* has a prominent place, the trails being found most useful in table decoration.

I could go on to write about other popular plants, but a general idea has been given of what has to be done in the Sandringham Gardens, and of the manner in which it is performed. On every side is learned the lesson of development. Animated by a desire to render the portion of the estate under his charge worthy of its great name in the highest sense of the term, Mr. MacKellar is doing all that skill, forethought, and energy can accomplish to make it second to none in the kingdom. The chance has come to him which every able and earnest man longs for—that of finding free scope for every good faculty and attribute. He is availing himself of the opportunity by work that is as enduring as it is excellent, and of which the fruits will be enjoyed for many years to come. The encouragement most dear to all gardeners, the interest and appreciation of his Royal employers, is not denied to him—indeed, its stimulus is felt by all workers, from the highest to the lowest. In the atmosphere of peace and contentment which reigns at sunny Sandringham is found a wholesome antidote to the evil suggestions of pessimism. Kind hearts in high places watch over the material comforts and mental pleasures of those who labour, brightening their lives with pleasant privileges and thoughtful acts; and so it is that the sunshine which spreads over the moors and woodlands finds its way into the hearts of those whose work lies amongst them.—W. P. W.

## TWO VERY OLD CARNATIONS.

IN looking over some old volumes of "Curtis's Botanical Magazine" lately I found in the volume for 1793 a coloured plate in excellent condition, with the colours as bright as when used, of what in those days was a wonderfully fine scarlet bizarre *Carnation* named *Franklin's Tartar*, raised by a Mr. Franklin, florist, of Lambeth Marsh, London, a district noted for florists a century and more since. It was considered to be so fine (and it must have been a very fine variety then, for it looks to be a good one now) by the Editor as to have earned the distinction of an illustration in a work in which florists' flowers found no place. Just 100 years have elapsed since this variety was figured.

In a later volume for 1814 there is a coloured illustration of the *Wheat-eared Carnation*, showing the main terminal flower, and one unopened bud only, every other lateral terminating with a *Wheat-ear* like growth, which did not produce the flowers. The colour is of a rosy crimson shade, with darker blotches, serrated edges, and such as our common border flowers are at this day. It is described by the Editor as "a monstrosity, occasioned by the multiplication of the parts of the calyx, and so extremely rare that the great botanist Linnæus remarked that he had hardly seen another instance of it, and he thought it of sufficient importance to give to this variety the name of *Dianthus Caryophyllus imbricatus*." The illustration was made from a bloom in the then famous nursery of Mr. Davy, King's Road, Chelsea. Dr. Hogg may probably have known this variety, and have a remembrance of Mr. Davy, who was so famous in the early part of the century for *Pelargoniums*; and there are old horticulturists who will remember his *Pelargonium Davyanum*. I for one can, and I seem to have some recollection of having seen the *Wheat-eared Carnation* when a boy.—W. D.

[Dr. Hogg remembers Mr. Davy very well, and has grown the *Wheat-eared Carnation*.]

## HARBINGERS OF SPRING.

THERE is every indication of a very forward spring this year. We had our share of rain in February, but the weather altogether was very open and mild. As a result, vegetation seems now springing into activity. Some of the earliest Pears are ready to burst their bloom buds, and also the Apricots and Peaches on walls. The tops of the lofty Elms, in which the rooks are busy building their nests, are assuming the dull sombre crimson shade so characteristic of the tree in the flowering season.

One of the local habitats of the wild Daffodil (*Narcissus pseudo-narcissus*), a place called St. Urian's Copse, near here, is now being ransacked, and lads and lassies are met coming home with bunches of half-open flowers of these Lent Lilies. Some also had flowers of the Marsh Marigold—*Caltha palustris*, or "King Cups," as they are locally called here. Yesterday (March 5th) I also saw two perfect specimens of the Painted Lady butterfly feeding from the flowers of the yellow Coltsfoot (*Tussilago Farfara*).

It may be interesting to know that on Saturday I picked several good Mushrooms out of doors on a sloping bank, wherein some manure had been dug in two years ago, and on the same day more Mushrooms were cut from an open garden near here, both being from a sandy soil—in fact, a drift of sea sand. No doubt the excessive wet had started the dormant spawn into growth, and the mild weather helped them to develop. They were certainly as fine and clean as any I obtained last summer. If we should be favoured with a little lower temperature and drying winds this month to check the somewhat forward buds, we may look for a very favourable fruit season.—C. ORCHARD, Bembridge, Isle of Wight.

## USEFUL APPLIANCES.

### ATKINSON'S LEAF SPONGER.

NOT many better helps, in a small way, to gardeners and amateurs are found than in the aphid brush—a pair of brushes face to face, and used in the form of tongs, for sweeping insects off *Roses* and plants; yet this simple appliance is not seen in every greenhouse and garden. Exactly similar in principle is another little help for washing the leaves of plants, "both sides at once." The "sponger" is just what its name implies, and explains itself in the small illustration (fig. 43). With a little practice there is no doubt that such plants as *Palms*, *Crotons*, *Orchids*, and others may be cleansed on both sides of the leaves with this appliance far more expeditiously than in the more tedious old way. The sponger is so simple that it is a wonder it has not been thought of before. It is sent to us by Messrs. Benton & Stone, horticultural brassfounders, Birmingham, and is presumably sold by sundriesmen. Improved syringes are also being introduced by the firm, worked by Stone's adjustable plunger. This plunger has an indiarubber case, with an outer case of cloth, both specially prepared. The prepared rubber ensures the elasticity necessary to produce constant sound working; the cloth retains the oil, ensures smoothness, and prevents corrosion of the rubber with the metal. By arrangement of plates, controlled by a thumb-screw, the plunger can be adjusted to the cylinder, to a perfectly water-tight pressure, and works with ease and smoothness.

FIG. 43.

## EARLY FLOWERING SHRUBS AT KEW.

**HAMAMELIS ARBOREA.**—There are three or four species of *Hamamelis* known in gardens, one, *H. virginica*, coming from North America and the others from Japan, all of them being perfectly hardy. The most ornamental of any, and the one generally recommended for planting, is the species here noted, which is now represented by flowering specimens in several parts of the Royal Gardens. It was introduced from Japan by a Dutch firm of nurserymen about thirty years ago, and although in its native country it is reported to attain a height of from 15 feet to 20 feet, it flowers quite profusely when only 2 or 3 feet high. At this season the plants are quite leafless, but the bright yellow flowers show up with marked effect against the dark, bare stems. To each flower there are four long, narrow petals which are curiously undulated and twisted, whilst the short, rounded lobes of the calyx are claret-coloured. The aspect of these plants (or, rather, small trees) thickly studded on all the younger branches with the bright, star-like flowers, is at this time of year especially pleasing, and they may be described as being as beautiful as they are curious. To the student of geographical botany the species is interesting as furnishing additional evidence of the marked affinity that exists between the floras of Japan and North America. The *Hamamelis* are popularly known as *Witch Hazels*; the oldest of them, *H. virginica*, which flowers in early winter, was known in English gardens 150 years ago.

**RHODODENDRON PRÆCOX.**—Shrubs flowering out of doors are just now so scarce that one possessing the beauty of this old garden hybrid is rendered especially worthy of notice. In the "American" garden (near the large Temperate House) there is an exceptionally fine specimen, a rounded bush 4 feet high, which is now thickly covered with flowers either partly or fully expanded. This *Rhododendron* was raised by Mr. Davies of Orm-kirk from the dwarf Himalayan species, *R. ciliatum*, crossed with *R. dahuricum*. I do not think there can be any question of its superiority from a horticultural standpoint to either of its parents, for it seems, in a great measure, to combine the good qualities of both. In foliage and habit it more nearly approaches *R. dahuricum*, but its leaves are larger and retained in greater number through the winter; *R. dahuricum* is, indeed, in some of its forms quite

deciduous. The flowers occur in clusters of three or four, and each one is  $1\frac{1}{2}$  inch in diameter, the colour being a bright pinkish purple. If we are favoured with mild weather for the next few weeks this plant will make one of the brightest pictures in the garden, although it must be said there is always the danger of a sharp frost (a few degrees do not materially affect them) prematurely destroying the flowers. For the greenhouse this hybrid is exceptionally valuable, being forced into flower at an early season by very little heat.

**DAPHNE MEZEREUM.**—During late years the popularity of this shrub appears to have in a great measure revived, and not only is the old typical form to be frequently seen, but several of the newer varieties are evidently becoming better known. Whether the species is indigenous to Britain or not is doubtful, but it occurs wild in several parts of England, although nowhere plentifully. Three hundred years ago it was grown by Gerard in his garden at Holborn, and is mentioned in the famous "Herbal" he published near the end of the sixteenth century. At any season of the year its quiet beauty and pleasant fragrance would, I consider, entitle it to a prominent place in the garden, but commencing to flower as it does in January and continuing through the two following months, its merits are very much enhanced. I have seen a plant 6 feet high, but it is only very old specimens that attain that size, and as a rule one sees them averaging from 2 to 3 feet. In well grown plants, which have been thoroughly ripened the previous summer and autumn, the shoots should be covered with the purplish red flowers for 6 inches to 9 inches of their length. The variety *grandiflora* has beautiful purple flowers of exceptional size, and some plants that we have of it have been in bloom since the beginning of the year. Another variety not very often seen has creamy white flowers; it is named *alba*. In cottage gardens, where occasionally very fine examples may be seen, the common *D. mezereum* is known as the Spurge Flax or Dwarf Bay.—W. J. B.

### MILDEW IN VINERIES.

MANY are the reasons assigned for mildew attacking Vines, such as drought at the roots, accompanied with a low moist atmosphere, insufficient ventilation, and so on. In my opinion, draughts of cold air blowing directly across the bunches at the time the Vines are in bloom is one of the causes, if not the principal one, of mildew. My experience is, that this fungus appears in nine cases out of ten when the berries are the size of Peas, and spreads rapidly over the stems of both bunch and berries if not checked by some means.

The method adopted by some persons of admitting air to houses during the time the Vines are in bloom is open to question. At the late varieties of Grapes are in flower (generally in April) hot sun, accompanied with cold east wind, is very often prevalent. Some cultivators are believers in admitting a free current of air to the vineries through the front ventilators, as well as by those at the top of the house, to effect a free dispersal of the pollen from the stigma. This manner of setting the Grapes may be in their opinion the best; but from experience I can positively say that it is the worst, and certainly one to be avoided by all those who prefer not to have a full crop of mildew to battle with. Last summer I saw many vineries badly infested with this pest, in some instances to such an extent as to render the whole crop useless. This was due in almost every case to indiscreet ventilation occasioning cold draughts of air to be blown directly across the bunches.

Many persons would feel some qualms as to whether the bunches would be afterwards presentable after being dredged over with flowers of sulphur. Even in the most careful of hands it is difficult to remove it entirely without leaving some trace behind. A safer plan, although perhaps not a surer cure, is to paint the stems of the Vines their whole length with flowers of sulphur mixed to about the consistency of paint, also the hot-water pipes, and sprinkle dry sulphur about the house. At the same time the pipes should be made quite hot, so as to throw off the sulphur fumes, which is fatal to the germs of mildew.

I do not scruple to dust any affected leaves with the sulphur as well, neither should I part a bunch if I found the presence of the mildew before the whole crop was affected. By keeping the temperature higher and the atmosphere drier by the aid of fire heat mildew can be stamped out of any vinery without the trouble of lifting the Vines, providing, of course, the attack is the result of a wrong method of ventilation. This subject crops up at an opportune moment, giving those persons who have but little experience an opportunity to guard against the admission of draughts of cold air direct to the bunches.—OBSERVER.

### PREVENTION BETTER THAN CURE.

HAD Mr. Thomas (page 169) but placed the above heading to his paper on mildew, he would perhaps have been nearer the mark. He admits that in his method of dealing with the plague of mildew on Vines there was nothing new, but at least he does very strongly emphasise the importance of doing the thing drastically, if done at all. At the best, however, Mr. Thomas does but recognise the fact that the sulphur treatment is only a palliative or temporary cure, and does not remove the predisposing cause of the disease, hence the great value of his concluding paragraph. Just as in humanity ninety-nine out of every hundred physical ills come from the stomach, so in plants or trees do the chief ills come from the roots. It is there where those who are in their gardens afflicted with vegetable ills should look primarily for causes.

Plants of all descriptions, if all be well at the roots, seem to have

inherent power to withstand atmospheric difficulties, but the moment there is anything wrong at the roots then they succumb. Even attacks of insect pests are never so harmful or difficult to cope with if all be well at the roots, as when all is wrong vegetable life can then do nothing to help get rid of the parasites. There can be no question but that in relation to roots, their functions, requirements, and foods, there is very much to be learned by the average gardener. Not all plant troubles, of course, are due to deficient root action; some, indeed, are due to too gross root action, when excessive sappiness does but make growth more amenable to diseases.—A. D.

### FRUIT FORCING.

**Vines.**—*Early Houses.*—When the Vines start very slowly and the bunches show a tendency to blindness, and others not advancing freely, they are certain indications of imperfectly formed buds, immature wood, and defective root action. Under such circumstances a slight increase of temperature and a reduced supply of moisture may be beneficial, but the only remedy is border renovation, encouraging growth and exposing it fully to light, with less close pruning. Thinning the berries should be kept well in hand, commencing as soon as those likely to swell freely can be detected, leaving the berries with room to attain their full size without wedging. Supply liquid manure to inside borders after the berries have been thinned, applying it in a tepid state. This, with a liberal supply of atmospheric moisture, especially at closing time, will materially assist the swelling of the Grapes. The winds are often sharp when the days are sunny, and every care should be taken to prevent sudden changes of temperature. Admit air carefully, closing early in the afternoon at 85°, so as to enclose the sun heat, and insure a good heat from that source in the latter part of the day, allowing the temperature to fall to 65° at night. Whilst stoning the Grapes are not materially benefited by a close, moist, and high temperature; but when the stoning is completed they swell rapidly, and should be encouraged by a moist atmosphere, liberal supplies of liquid manure at the roots, ventilating early and closing in the afternoon. Continue this until the Grapes change colour, when they must have air more freely. Keep the laterals properly regulated, but allow some extension, as every leaf encourages root action, and it is necessary to maintain that for a due supply of nourishment, with the foliage fully exposed to light for its assimilation.

*Fruiting Vines in Pots.*—These must sustain no check through dryness at the roots or want of food, supplying liquid manure liberally, surfacing the pots with rich material, and if the roots extend beyond the pots feed them there as well as in the pots.

*Succession Houses.*—The Vines started early in the year are now in flower, and a rather dry atmosphere, with a free circulation of air, and a temperature of 65° to 70° at night and 70° to 75° by day artificially, advancing 10° to 15° from sun heat, are conducive to a good set. Maintain a moderate moisture by damping the house two or three times a day in bright weather. Any shy-setting varieties, such as Muscats, should be kept 5° higher, the flowers being carefully fertilised with pollen taken from the free-setting varieties, as Black Hamburgs. The Vines started at the beginning of last month will require attention for disbudding and securing the growths as they advance, stopping the shoots two joints beyond the bunch where the space is limited, but where there is room allow extension. Remove all superfluous and ill-formed bunches of the free-setting varieties as soon as those that are most promising for the crop can be determined, and those of the shy-setting should be reduced in a similar manner after they are sufficiently advanced for deciding on the best likely to mature.

*Late Houses.*—The midseason varieties intended to afford Grapes in August forward should now be started. Late Hamburgs, however, may be kept cool and not started until next month. Muscats, Alicantes, Lady Downe's, and other late varieties should be encouraged to move now, as they require a long season to grow and perfect their fruit, which should be effected early in September for the Grapes to keep satisfactorily. Inside borders must be brought into a thoroughly moist state by the application of water, but a saturated condition is not advisable, as it hinders rather than assists root formation. Outside borders will not require more than a light mulch of lumpy, partially decayed manure. The atmosphere should be kept moist by damping the Vine rods and every available surface two or three times a day, 50° being a sufficiently high night temperature, 55° by day artificially, and 65° with sun. Young canes should be depressed to insure their pushing the buds evenly to the base.

*Vines Raised from Eyes.*—The "eyes" inserted as before advised will now be well rooted, and should be shifted into 6-inch pots, placing them on shelves of stone or slate over the hot-water pipes in preference to plunging in bottom heat. Syringe tepid water well amongst them and pinch the laterals at the first leaf. The canes should be trained to wires about 1 foot from the glass.

*Cut-back Vines.*—Vines cut back for fruiting in pots next season will now have made a little fresh growth and be fit for shaking out and

repotting. If they have been plunged in bottom heat they should be returned to it for a time, 75° to 80° being sufficient, but otherwise bottom heat is not necessary. Clean pots and efficient drainage should always be provided in Vine culture. Cut-back Vines will be accommodated in 7-inch pots; those that were shaken out some time ago, potted in that size, have filled the pots with roots and made 18 inches or more of cane, should be shifted into 12-inch pots, potting firmly. Good turfy yellow loam, with a 9-inch potful of steamed bonemeal, a similar quantity of soot, and double the amount of wood ashes to 3 bushels of loam, mixed, form a good compost for Vines in pots. If the loam be rather strong add a sixth part of old mortar rubbish. Keep the Vines rather close and moderately moist until they are established. Train the canes near the glass, as they cannot have too much light, it being important that the growth be solidified as it is made, and the laterals should be repressed so as to concentrate the vigour on the principal leaves, which must be kept clean.

**Pines.—Suckers.**—The rooting of these after potting and placing in a close moist pit in bottom heat will be indicated by the growth of the foliage, but it is as well to turn the plants out of the pots so as to ascertain the condition of the soil and the roots. Those issuing from the suckers or plants subjected to similar treatment are very tender and susceptible to injury from the effect of too much bottom heat, hence when they reach the sides of the pots a temperature of 85° is ample, above which there is danger. When the bottom heat is more than that the pots should be raised, placing some loose tan under and around them, so as to allow the superabundant heat to pass away. The plants must not be neglected for water at the roots, but none must be given until it is required, and then a full supply, always tepid, with some stimulant held in solution, as guano, 1 lb. to 20 gallons of water.

**Potting Plants.**—Young stock will now make roots rapidly, therefore have soil in readiness for transferring them to the fruiting pots, it being important that they be grown without a check. Sound fibrous yellow or hazel loam in good sized lumps is the best material for potting, pressing it firmly round the roots of the plants, watering the plants with tepid water, and plunging them in a bottom heat of 90° to 95° until the roots have possession of the fresh soil, when 85° is more suitable.

**Fruiting Plants.**—These and others that are near the flowering state should have a night temperature of 65° to 70°, and 75° by day, with 80° to 90° from sun heat, closing at 85°, well damping all available surfaces in the house at the time. The plants may be lightly sprinkled occasionally, but not when they are in flower. Similar remarks apply to successional plants as regards damping the house and sprinkling the plants overhead, affording them a bottom heat of about 85°.

#### THE FLOWER GARDEN.

**Tuberous Begonias.**—It is a great mistake to leave the seedlings in the pan long after they have formed their first leaves. They can be readily moved with a very small stick having a forked point, this being inserted under the leaves, another pointed stick being used for loosening the soil about the roots. Use a light soil, and place the seedlings about an inch apart in pans. Give a gentle watering, cover with squares of glass, place on a warm stage or shelf in a forcing house, and shade carefully from strong sunshine. After about three days tilt the glass slightly. When nearly touching each other remove them to larger boxes, disposing the plants 3 inches apart each way. They ought still to be kept in gentle heat, and if extra fine plants are required for bedding out transplant to a pit or frame where the benefit of mild bottom heat will be received. On no account place seedling Begonias in small pots, this effectually stunting them.

**Old Begonia Tubers.**—These do not start nearly so well when placed in pots as they do in boxes or beds of moderately rich soil, or a mixture of fresh loam, leaf soil, and old Mushroom bed manure. Last year's bulbs are the best for giving a display of extra fine flowers, and there should be no coddling resorted to. All would start naturally in a pit or frame from which frosts were excluded, and if disposed not less than 6 inches apart each way fine plants will be ready for the beds early in June. Older bulbs may be similarly treated, but if the variety is worth preserving it would pay well for being split into as many pieces as can be had with a shoot attached. Start these in gentle heat, divide when the shoots are about 2 inches long, return the divisions to boxes, and keep in gentle heat till they are rooting strongly.

**Begonia Weltoniensis.**—There are several species of Begonias that succeed fairly well bedded out; but, as a rule, they compare badly with the tuberous-rooted section. The old B. Weltoniensis is a noteworthy exception, the habit, foliage, and flowers all being good, a neat circular bed filled with this variety and edged with blue Lobelia being a welcome change. If any old plants have been wintered under a greenhouse stage remove what long ends there may be attached, start in gentle heat, and take off and place the cuttings in heat. When rooted top them, and soon after either place singly in 2½-inch pots or in boxes. If stopped a second time neat bushy plants will be available by the end of May.

**Two Good Blue Flowers.**—Blue flowers are always scarce, but two old plants which give flowers of the richest blue colour are *Salvia patens* and *Delphinium formosum*. The former has roots much resembling those of Dahlias, and being wintered in a very similar manner can be made to produce cuttings freely now. Placed in boxes of soil and given the benefit of gentle heat shoots will be produced from the base, and these should be detached and rooted in a heated frame. Top the rooted cuttings, pot singly, and otherwise treat similarly to Dahlias. The old roots may be divided, and also planted out. *Delphinium formosum* is very effective, and if raised from seed now the plants will

flower this summer, and much more strongly next year. Sow in a pan of light soil, place in brisk heat, prick out the seedlings in other pans or boxes of good soil, and duly harden off and plant out. If wanted to flower late top the plants once, otherwise there should be no stopping.

**Shrubby Calceolarias.**—If these have been wintered in frames or pits, and either in boxes or in a bed of soil, the plants will now be growing strongly. The tops most probably are long enough for making into cuttings, and will sometimes root fairly well in gentle heat, though spring-struck plants are rarely so serviceable as those rooted in the autumn. Cuttings not being wanted top all the plants, and by the time they have broken afresh it will perhaps be convenient and safe to bed them out temporarily.

**Violas and Pansies.**—It is most unwise to coddle these plants, and it ought soon to be possible to wholly dispense with the lights now over them. Supposing that it is not possible to place them soon where they are to flower, and also that the plants at present are not more than 2 inches apart each way, they must soon be temporarily bedded out 4 inches asunder, where they will develop into sturdy plants ready for the beds early in May. For a later display of Pansies sow seed thinly in pans or boxes any time during March or early in April. It will germinate readily in gentle heat, and if the plants are rather plentiful prick them out early in other boxes of good soil, and from these transfer to the open beds or borders.

**Sweet Peas.**—Most of the newer varieties are best sown under glass. Planting out of pots seems also to favour a strong branching and more continuous habit of flowering than is the case when the seeds are sown where the plants are to grow. Four or five seeds in each 3-inch pot are enough, and these germinate quickly in a brisk heat. If those sown in the open are coming up badly sow more seed in pots, and when the plants have been duly hardened off make good the gaps with these.

**Mignonette.**—Early sowings of Mignonette are often a failure in the open, and the surest way of having an early supply is to sow seed thinly in small pots, placing these in heat. Early reduce the seedlings to three or four in a pot, harden off, and plant out before the soil is crowded with roots.

#### PLANT HOUSES.

**Carnations.**—Plants that have been wintered in cold frames and are well rooted may be transferred into larger pots if they are wanted for flowering under glass. Place these plants singly in 6-inch pots, or two or three in 8 and 9-inch pots. After potting return them to frames, or a cool, light airy house, placing the pots on moisture-holding material. If frost is kept from them they will soon start into growth. Directly aphides make their appearance fumigate with tobacco smoke. These plants do well in good loam, one-seventh of decayed manure, and coarse sand. Cuttings of Miss Jolliffe that have been in a cool house may be taken off and inserted in sandy soil in pots or in a box and covered with a square of glass. If the box containing the cuttings is stood where they can enjoy slight bottom heat they will quickly form roots.

**Primulas.**—To produce plants for early flowering sow seed now in light soil passed through a fine sieve, so that an even surface can be made. The seeds should be barely covered and then watered lightly with a fine-rose can. Cover the pan with a square of glass and a sheet of paper and place in a temperature of 65°. *P. obconica* may also be sown, but do not cover the seed with soil.

**Celosias.**—For an early batch seed may be sown without delay, just covering it. Where Cockseombs, Balsams, Petunias, and other similar plants are appreciated sow seed in small quantities.

**Heliotropes.**—Where standards are appreciated cuttings of soft wood should be inserted in 5-inch pots without delay. The cuttings will root freely under hand-lights in a warm house. Young plants established in 5-inch pots will soon commence flowering freely if placed in a light house where a temperature of 55° can be given them. Plants that have become straggling may be cut back for succession.

**Solanums.**—These should be pruned back and placed in a heated structure until they break into growth. When this takes place reduce the old balls and repot the plants. Seedlings or plants raised by cuttings and established in 2-inch pots may be placed into larger pots. Keep these growing on in an intermediate temperature.

**Prunus sinensis.**—Plants that have flowered may be pruned closely and stood in a Peach house at work until they start into growth, when repot if they need more root room. If the plants are in pots large enough reduce the balls by one-third, and place them again into others of the same size. Cuttings of young wood taken off close to where they issue from the old stem root freely in sandy soil under bellglasses in heat.

**Deutzia gracilis.**—Cuttings may be taken from any plants that have young soft growths upon them if an increase of stock is needed. These cuttings root freely in sandy soil, and may afterwards be planted in boxes a few inches apart. After the young plants are rooted the point of the leading shoot should be removed to induce them to branch. Capital little plants will be produced by the time the weather is sufficiently genial for planting them outside.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### VICIOUS BEES.

SOME bee-keepers manage to work amongst and manipulate their bees without protectors, and in a way that does not irritate the bees; while others have always to be veiled when approaching them. The manner, movements, and odour of the bee-keeper have much to do with spiteful bees. We have heard much about the spitefulness of Punic bees, but it is noteworthy to state that during all the many manipulations I had at home with them last summer I never donned a veil, and only occasionally used carbolic acid for the purpose of dispersing the bees. As a precaution at the moors I sometimes used a veil, but when unveiled I found a safe retreat close to the strongest hives. It is, however, safer to be protected, because one stinging bee irritates many, and when so enraged weeks may elapse before they are subdued. The accidental killing of one bee will also at times be the means of infuriating a whole apiary of bees. In spite of this, an American bee-keeper advises killing bees when inclined to sting, and for that purpose he recommends the use of two flat boards, but does not say how that is to be accomplished. Besides, the advice is absurd, for frequently have I fetched vicious bees from apiaries to my own, and before many hours were past they were as mild-tempered as one could wish for.

### PROLIFIC QUEENS.

Much the same as the foregoing advice is that of breeding prolific queens. I defy anyone to lay down rules as to how to breed queens to any reliable standard of prolificness. That is also beyond human power, unless it be in certain crosses or particular breeds of bees. Bees sometimes frustrate the efforts of the queen by eating her eggs as they are laid. Frequently have I changed a queen from a hive that made no progress to another hive, when a new régime was at once begun, and with satisfactory results. It is wise for the bee-keeper either to effect a change or supersede the queen that does not give satisfaction, but he must dismiss from his mind the possibility of raising queens to a certain standard of perfection and usefulness.

### THE WEATHER.

On the 26th ult. we had 5 inches of snow, a mile northwards there being double that depth. On the morning following the thermometer stood at 15°, then on the following day another 5 inches of snow fell, but it was soon dissipated by a westerly wind. The low temperature keeps the bees within doors, not even venturing out to work on the pease-meal. With the exception of the 19th no pollen has as yet been gathered. The high winds have stripped the Willows of many catkins. The forced confinement is to the advantage of both bees and bee-keeper, as the adult population will be spared, and in more strength when milder spring comes.

### FEEDING BEES.

Since January, the 19th of February was the only day bees could be fed with safety; nor until the temperature reaches 60° will I attempt feeding. Although I do not feed bees, as a rule, till May, I shall between the present time and the fruit blossom period give some of my bees several pounds of sugar, in order to prevent early breeders "drawing" their brood.

In the south of England and other places it is sometimes absolutely necessary to have hives earlier than in later districts, in order to insure strong hives and a heavy yield of honey. A few pounds of sugar given now insures the hatching of all eggs laid, uniting two swarms, and distributes the brood combs of a number of the colonies amongst the others about a month before the honey yield. That plan is as satisfactory and remunerative as the old one of working two queens in one hive, obviating the necessity of having cumbersome hives, which militates against profitable bee-keeping in other respects.

### HIVES.

Those who take their bees to the Heather a considerable distance will find it impracticable to move about the "standard" hives, if of sufficient size for two queens. The hives I used for that purpose were made to expand laterally, and are suitable for wintering two queens, expanding in summer, then storifying when moved to the Heather, so that the superficies of the hives were reduced to the lowest possible size.

I exhibited this hive before the Caledonian Apiarian Society along with Mr. Abbott's, when he acted as Judge. At the next Show of the same Society in 1876 I was awarded first prize, and for many years after. I also showed it during the Jubilee year of the Highland and Agriculture Society at Edinburgh, and altogether have secured many prizes.—A LANARKSHIRE BEE KEEPER.

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Address (F. P.).**—The address of Messrs. Bell & Son, as has often appeared in their advertisements, is York Street, Covent Garden, London.

**Cinerarias (L. C. P.).**—It is better in the case of nine Cineraria plants out of ten not to pinch off their leading shoot at this season, but let it extend for flowering.

**Gladioli (F. J.).**—The following are good and inexpensive varieties:—Amalthée, Amitié, Bicolore, Dalila, Flamboyant, Meyerbeer, Opale, Pasteur, Phoenix, Sultana, Shakespeare, Peresita. They will supply flowers from July till October.

**Secretarial Duties (Member).**—Obviously we cannot particularise, but undoubtedly the cardinal duty of a paid Secretary is to carry out the wishes of the Committee whose servant he is. Such an official taking an active part, privately or otherwise, against any member of Committee nominated for a particular position in a society, would render himself obnoxious to other members, and also lay himself open to the charge of disloyalty, but we do not know that any such case has been proved to exist.

**Forced Lilac not Scented (Mrs. M.).**—The spray of Lilac sent is one of the Siberian kinds, but too crushed to distinguish the variety; both the purple and white forms are, however, practically scentless, especially when forced. The flowers are produced from the flower buds formed the previous year, and foliage rarely appears with them under very early forcing. This particular kind is always very shy in this respect. The best Lilac for forcing is Charles X, but this if very early rarely produces foliage, but later it does so freely. The white form Virginalis is good for forcing, and generally produces foliage freely even early in the season.

**Analysis of Celery (W. Spence).**—The following analysis is given in "Food," by A. H. Church, M.A., Oxon:—

CELERY.							
		In 100 parts.	Oz.	In 1 lb.	Gr.		
Water	..	93.3	..	14	..	406	
Albumen	..	1.2	..	0	..	84	
Mucilage and starch	..	1.6	..	0	..	112	
Sugar	..	2.2	..	0	..	154	
Cellulose	..	0.9	..	0	..	63	
Mineral matter	..	0.8	..	0	..	56	

For one part of flesh-formers in Celery there are about three parts of heat-givers, reckoned as starch. According to Wolff in his "Aschen Analysen," Celery takes from the soil the following ingredients represented in per-centages:—Potash, 38.16; soda, 19.33; lime, 13.8; magnesia, 1.41; iron, 5.82; phosphorus, 13.67; sulphur, 3.34; silicon, 2.75; chlorine, 18.51. These are the average results of two analyses.

**Seakale Stems Scabbed (F. M.).**—The root-stems are affected with a fungus, similar to if not identical with that producing brown patches or scabs in Potatoes—namely, *Tubercinia scabies*, but there is also evidence of the substance of the roots being eaten by the larvæ of some pest, evidently those of the snake millipede (*Julus pulchellus*). We advise the ground to be trenched 2 feet deep, but if there is only a mere crust of good soil the ground should only be stirred to the depth named. A dressing of kainit, 2 lbs. per rod, should be given the trenched or stirred soil, applying it in the autumn or early in the spring, distributing it evenly and leaving it for the rains to wash in. The "sets" must have all the decayed parts cut away, be dipped in a solution of kainit, 1 oz. to a gallon of water, then stood root downwards to dry, afterwards planting, say in spring, and when that is done, or when the plants show the least signs of growth, apply the following mixture—superphosphate 1½ lb., nitrate of soda 1 lb. (this being in fine powder) mixed, per rod.

**Hyacinths Falling (Subscriber).**—The cause is evidently local, and must be sought for on the spot. The bulbs were good, and the treatment, at least until the plants were removed from the frame, appears to have been correct. The soil sent contains no destructive larvæ, and, as you say, "fine healthy roots formed in it," we conclude it was suitable for its purpose. The crowns started strongly, but eventually the roots perished, and growth consequently ceased. Have the plants always been watered by yourself? is the first question that suggests itself; and the second is, Has any stimulant been dissolved in the water? We have seen the tender roots destroyed in exactly the same way by an overdose of sulphate of ammonia, and we cannot think otherwise than that these Hyacinths have had something applied by someone with, presumably, the best intentions, which has had an unfortunate effect.

**Scale on Pear Trees (S. S.).**—The recipe you name is perfectly safe, as the lime will prevent any deleterious effects likely to follow the use of soft soap at the rate of nearly 1 lb. to the gallon of water. The recipe: "3½ lbs. soft soap, 14 quarts water, with enough quicklime slaked to make a thick paint, and every part of the tree to be dressed with composition," must be carried out without deviation. It is M. Du Breuil's recipe.

**Naming Molluscs (G. McD.).**—Though an authority has been consulted on the specimen you sent with the object of determining the species, the result is not satisfactory through the sample not being in sufficiently good condition for the purpose. As you appear to have several species that you wish to have named, probably the best method of attaining your object would be through the agency of such a journal as "Science Gossip." It is a question for specialists, and not within the province of gardening publications, which only deal with predatory visitors that are in more or less close connection with plants or garden crops. Your specimen does not come within this category.

**Span-roofed Pit (F. J.).**—A three-quarter span would be the best for winter, but as that is the least important period of the year, a span-roofed pit would be better for the position. As you require the pit for growing Cucumbers or Melons in summer the brickwork should not be less than 2 feet 6 inches in height, say 18 inches below and 12 inches above ground, and beyond a 14-inch and a 9-inch course of brickwork as a footing, the wall may be 4½ inches built in cement. This is firmer than 9 inches built in mortar, and that amount of space is gained as standage for plants. The depth named will be sufficient for about 18 inches of fermenting material desirable for bottom heat to the Melon or Cucumber plants, the soil being placed in the centre, say a barrowload in each light.

**Plants for Growing on the Roof of a Building (Librarian).**—We suppose the roof is flat or otherwise suitable for the standage of plants in pots or tubs. The chief point to attend to is securing them in position. Amongst plants that generally succeed well, Zonal Pelargoniums of various sorts perhaps take the first place, then Fuchsias, Petunias, Heliotropes, with Tropæolums of various kinds as trailers. Those are only available for summer. If you want plants that will stand the year round you must have recourse to Saxifrages, Sedums, and Sempervivums, some of which do admirably on housetops, the common Houseleek and London Pride (*Saxifraga umbrosa*) revelling amid the smoke of towns. Chrysanthemums answer well in the autumn, and bulbs in the spring.

**Insects on Pear Wood (J. Hiam).**—The five insects only just visible to the unaided eye as blackish specks are evidently the perfect form of the Pear gall mite (*Phytoptus pyri*, or *Typhlodromus pyri*, *Scheuten*), with six legs. The late Mr. Andrew Murray believed this form to be a Gamasus, but larvæ of the gall mites differ from the adults in being much longer and narrower and only having four legs, some of the adults having twice that number. The whereabouts of this eight-legged mite from the fall of the leaf until the re-appearance of fresh leaves, in which the *Phytoptus* lives and forms spots or galls, has never been satisfactorily ascertained; this, however, is now manifest, and we are obliged by the specimen. The thickening of the Pear shoots is not due to canker caused by the fungus (*Nectria ditissima*). We should like to have one or more young shoots of the current year with leaves, especially those exhibiting reddish or brownish spots, say in August, and if there are raised pustules on the young wood all the better for our purpose. The thickening of Pear tree twigs is due to the same cause as that of Apple trees. The twigs are malformed, but not affected with canker, a very common occurrence in old or full grown orchard Apple and Pear trees, which in bad cases have a tendency to form "witch knots," as in Birch, Hornbeam, and certain other trees. These deformities, however, are caused by fungi, but the gall mites often cause a diseased condition of the growths, similar to a young "witch knot," and not unfrequent in old Apple and Pear trees.

**Peaches Infested with Mildew (R. H. S.).**—The dense greyish patches on the skin of the fruits are the growths of a mildew, *Oidium leuconium*, an early condition of the fungus *Sphaerotheca pannosa*, which is very common on Roses in some localities, and on Peach growth and fruits. It first appears as a minute roundish speck of whitish powder, slightly raised on the skin, and rapidly spreads over the fruit, living on the outer surface of the cells. The patches often cover a considerable portion of the fruits, those badly infested falling, whilst others which do not fall swell irregularly, are sometimes useless. Happily, the mildew succumbs to early treatment with flowers of sulphur dusted on the affected parts; but it is best overcome by sulphur in solution, either in the form of bisulphide of calcium or sulphide of potassium. These can be had at the chemist, but they must be fresh, employing half an ounce to a gallon of water, and syringing on the trees, repeating as necessary. We use the bisulphide of calcium made after the following formula:—"Flowers of sulphur 1 lb., quicklime 1 lb. Slake the lime in a pan, add the sulphur and a gallon of water. Incorporate thoroughly, heat, and boil gently for a quarter of an hour, keeping constantly stirred. Allow it to settle, and when cool pour the supernatant liquid into a stone bottle, and keep it well corked. For use, mix a pint with 12 gallons of water, or a quarter of a pint in 3 gallons." Spray the trees liable to mildew before any signs of the disease appear, and always before the leaves are 2 inches long, continuing the spraying at fortnightly intervals until the foliage is well developed, when there is little to fear from mildew. Evening is the best time to apply the solution. In cases of attack act promptly with two or three forcible sprayings on alternate evenings. Syringing may be practised instead of spraying, but the latter is more effectual and economical. An occasional forcible syringing with clear water should

be given the trees, one good syringing being more effectual than many sprinklings in washing off and destroying the spores, and where syringing is properly attended to there is little or no mildew on Peach trees under glass. Where syringing or spraying is undesirable on account of plants flowers of sulphur should be freely dusted on the trees, especially on the affected parts, and rubbed on the parts of the fruit infested with mildew gently with the finger. That will arrest the spread of the mildew; but it is better to prevent its attacks than to apply remedies, for none will efface the effects. See that there is no deficiency of moisture at the roots of the trees, and afford thorough supplies of water or liquid manure when needed. A renewal, wholly or in part, of the soil of the border early in the autumn to induce a better rooting system might be of great benefit. Read attentively Mr. Owen Thomas's article on page 169 last week.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. —(R. C.).—*Æschynanthus cordifolius*.

#### "FARMING."

SOUND practice and profitable results are both implied by this expressive term; very little difference of opinion is there about the profits, but there certainly are widely different concep-

tions of what constitutes sound practice. To these in a variety of ways expression is given in farm management, aye! and of farm mismanagement too, a mere custom and prejudice very frequently proving an irresistible inducement to the persistent cultivation of crops upon which profit is impossible, to the neglect of, or rather the improper feeding and general care, of live stock. Surely it is high time that there was an end of such folly. What is wanted is more common sense in every detail of farming—better practice on the farm, more business aptitude in the farmer. Entirely did we agree with a recent writer in the *Agricultural Gazette*, who said plainly to farmers, "Do away with the middleman, who is no good to us, and takes what little profit there is."

"Do away with your cake merchant, and use the produce of the farm instead. It seems folly to use cake with all the goodness squeezed out, to give £8 or £9 a ton for the husk, and sell our produce at an average of £5 or £6 per ton."

"Avoid auction marts and butchers' and dealers' 'rings.' They are bound to 'best' us, and why should we give an auctioneer 5s. for selling an animal we are capable of selling ourselves?"

This is clearly the right view of things, but it is only the inception of a change that must be thorough in every way if it is to be successful. Cake, hay, and roots, nutritious as they are when used in judicious mixture, are three of the most costly components of sheep or cattle dietary, not one of them being indispensable. Substitutes? Undoubtedly, and excellent ones, too, have we in silage, Oats, and Oat straw. If it comes to a question of "farming," compare the process of ensilage with that of haymaking. In the one we have simply to mow, cart, stack, and compress; in the other at best there is the mowing, tedding, collecting, carting, and stacking. This can only be done expeditiously in exceptionally favourable weather; with weather at all unsettled the process becomes tedious and costly—frequently exceedingly so; the hay then in the process of "making" loses much of its nutritive property, becoming in a very wet summer so poor in quality as to be very little better than litter. None of this loss in feeding value ever occurs in well managed silage. It is true enough that there is some waste on the outside of a silage stack, but the bulk of it is sound, wholesome, and highly nutritious food.

Another point is bulk of crop. "Farming" means a full crop, and nothing short of it. Do farmers generally obtain a full crop from permanent pasture? Do they get a full early bite, or an abundant aftermath? Is their pasture of the verdant hue in winter which alone betokens land well drained, fertility fully sustained? Assuredly not. Every winter there are tens of thousands of acres of it throughout the length and breadth of the land of that brown hue which proclaims the poverty of the soil, the ignorance and folly of those who own or hire it. It is but the repetition of an oft told tale, to point to sheep folding and chemical manures as a certain remedy for so lamentable a state of things. If we would have full forage crops of every sort we must have sustained fertility, not soil exhaustion. The cause of exhaustion is so certain, the remedy so simple and so sure, that really poor pasture ought to be as much the exception as it assuredly is now the rule. It was positively refreshing to hear from a correspondent of the success which had followed his use of chemical manures, because we still hear frequent expressions of doubt about them, or assertions that they are worthless. "Stimulants are they, and nothing more," said the agent of a large estate to us recently. No clear response did he make to our challenge for proofs; he just had recourse to mere assertion. Plenty of facts had we of the high value of pure nitrogenous and mineral manures in judicious combination, facts which we hope carried conviction with them, as they have so frequently done.

The thorough, intelligent, cultivation of permanent pasture

is a point of husbandry, a branch of "farming," which points to profit in no uncertain manner. Now is the time to begin by a wise outlay of capital upon the purchase of manures, which store the soil about the grass roots with those essential elements of plant foods—nitrogen, potash, and phosphoric acid. To apply them now in the form of nitrate of soda, superphosphate, steamed bone flour, and muriate of potash, so far as means admit, would be a good beginning, and the good work could then be carried on next winter by means of sheep folds on every upland farm where sheep winter well.

#### WORK ON THE HOME FARM.

Early lambs have been folded with the ewes on Swedes which had from the first enough leaves for the lambs to run forward and eat. They now do much more than nibble tops, quite half of many of the roots being eaten before the ewes get to them. This is right, for with sound nutritious trough food health and condition are alike satisfactory. The wrong part of folding is in turning pregnant ewes upon Turnips and giving very little corn or chaff. As a general rule we allow no Turnips of any sort to be used for the ewes till after the lambing. In skilful hands a few Turnips do no harm before the lambing, but owing to the general tendency to use them in excess of what is prudent we allow none to be used. The reason for this may as well be given once more—i.e., that the consumption of large quantities of such cold watery food by pregnant ewes makes so severe a tax upon the system that it weakens instead of nourishing them, causing abortion as well as losses among them so frequently that it has long been thought "good luck" if only an occasional ewe dies. In many a flock lambing does not begin till the middle of March; keep such ewes from Turnips, keep them out of muddy folds. Pasture, silage, and crushed corn will keep them strong and healthy. Beware of cold cutting winds; they are often fatal to young lambs. Give full attention to providing shelter that is thorough and food that is wholesome. Trust nothing to luck or chance, let it be the shepherd's aim to rear every lamb; he may not succeed, but then he may, and whatever be the result the effort to excel makes a man more skilful, enables him to grasp something more of cause and effect, to do better now and in future than he has done in the past.

Most disheartening is it to see the wretched plight of so many store beasts. It is wrong, we say it emphatically, in the grazier's interest, and nothing he can say will make it right. To compel cattle in a state of semi-starvation to clear a pasture of "fog," which in plain English is innutritious grass, mostly brown, is certainly not "farming." Wholesome food and shelter they must have to winter well and come out in fresh condition in spring. Silage, Oat straw, and kibbled Oats, with some Cabbage or Thousand-headed Kale, is the best dietary for store cattle in winter. All of it is grown upon the home farm; there are no cake bills. We cannot afford them, and the hay is reserved for dairy cows and light horses. Pasture herbage is growing so freely that we hope to be able to turn out early this spring.

#### OUR LETTER BOX.

**Chemical Manure for Pasture (W. R. W.).**—By all means repeat the dressing which answered so well in 1890. In the later prescription to which you refer nitrate of potash is simply given as having answered well. We ceased using it because it was so expensive, and also because we had found an efficient substitute in muriate of potash at about one-third the cost of the nitrate. We are glad to know that you derive help from our farm notes.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

- 26th.—Gale, and steady heavy rain from 7 A.M. to 1 P.M.; generally sunny in the afternoon; rain and hail about 5 P.M., bright again after.  
 27th.—Bright early; overcast after 9 A.M., and almost incessant rain from 11 A.M. to 11 P.M., heavy from 11.30 A.M. to 3 P.M.  
 28th.—Rain in the small hours; bright sunshine from sunrise to 3.30 P.M., then slight fog till evening.  
 1st.—Heavy rain from 8.30 A.M. to 10 A.M.; generally sunny after 11.45 A.M., but showery between 2 and 3 P.M. 2nd.—Fine, and frequently sunny throughout.  
 3rd.—Rain about 3 A.M.; overcast day, with a little drizzle in evening.  
 4th.—Rain from midnight to 3 A.M.; overcast, with frequent drizzle in the morning; bright sunshine in afternoon, fine night.  
 Another mild and wet week.—G. J. SYMONS.

THIS week's *Journal of Horticulture* (March 9th) is to hand, and it has "roused" me to say a word or two in a very friendly spirit. I feel sorry the excellent and worthy estate manager, who has told us his mind on page 191, should be so bitter. He mixes up foxhounds, keepers, unjust stewards, and incompetent landlords in rather a funny manner. It does take a great deal of money to hunt the country, but your correspondent seems to forget how and where the money goes. Directly and indirectly the farmer gets hold of some (of course he could do with more), but the day of small things is not to be despised. It is a pity to let good gardens go, but between ourselves are they not sometimes very expensive hobbies, and only maintained for the benefit of outsiders? I am afraid that if landowners had strained every energy to understand their land even that would have gone but a very small way to have kept them clear of present difficulties. I am acquainted, as are other readers of your *Journal*, with large holdings where all that skill backed by money has been done, and even there the end has been the *Gazette*.

Again, Mr. Editor, I quite agree with you as to the ill-adapted men who fill (or, rather, do not fill) the post of agent on many estates; but remember, on a large estate with capitalists and University men as tenants, a man their own equal in point of birth is a necessity. A man of the people, however clever, lacks that *savoir faire* without which there will always be friction between the two parties. I come of a farmer and agent-producing stock, and am convinced that the most successful steward is one born and bred to the profession. He at any rate knows his business, and his first object is to conduct it well.
